Alberta Electoral Boundaries Audit — Comprehensive Forensic Audit Monograph

A symmetric, reproducible forensic assessment of the 2025–26 Electoral Boundaries Commission's majority and minority recommendations

WILL CONNER · MOUNT ROYAL UNIVERSITY, BSC COMPUTER INFORMATION SYSTEMS

Draft — November 2026 · Non-partisan · Repository · Data and scripts linked throughout

Funding: *This research received no external funding. All costs were borne by the author.* ***Competing interests:*** *The author declares no competing interests beyond the relationships disclosed below.* ***Institutional affiliation:*** *The author is a student at Mount Royal University. This research was conducted independently and was not commissioned as coursework. The views expressed are the author's own and do not represent Mount Royal University.* ***Relationships:*** *The author has worked as a contract election officer for Elections Alberta for about 27 years, election by election, administering the vote on election day. The author is not under contract now and last worked at a recent election. The author has had no other employment with Elections Alberta, has no knowledge of its work beyond those tasks, and drew nothing in this audit from that work; every input is public. This research is the author's own, not Elections Alberta's, and does not speak for it. The author has no employment, contractual, or advisory relationship with the Electoral Boundaries Commission or any provincial political party. The author has voted for and donated to both conservative and progressive provincial parties in Alberta as an adult. Neither the NDP nor the UCP has been contacted about this research at any stage, and*

neither party has had any involvement in or advance knowledge of it. No compensation was received from any party. The only individuals with substantive knowledge of the audit's findings and methodology prior to publication are volunteer reviewers at Mount Royal University; this does not constitute institutional endorsement or involvement by MRU. Elections Alberta's GIS team was made aware of the research through the author's formal shapefile request and provided data access and technical assistance (2026-05-06 and 2026-05-07); Elections Alberta has not been shown the audit's findings or conclusions. The methodology was applied symmetrically to both maps; which parts were written down before their results, and which after, is set out in §4.3.3.

Pre-publication status. *This monograph has not been publicly released. Integration of canonical Elections Alberta shapefiles (received 2026-05-06) is ongoing; individual section results may shift as recomputation continues. The codebase is also undergoing cleanup and script-count reduction. Do not cite, quote, or distribute without confirming the current status of the specific finding.*

Executive summary and reading guide

This document is a **comprehensive forensic audit monograph**, not a single-topic journal article. It covers three distinct lines of work sharing a single dataset and methodology, and it runs substantially longer than a standard journal submission. Readers short on time should use the guide below to jump directly to the part matching their question. Readers who need the full evidentiary chain should read end-to-end.

Headline finding (read this if you read nothing else). Alberta's 2025–26 Electoral Boundaries Commission produced two competing 89-seat maps on March 23, 2026. This audit evaluates both proposals using identical methods applied symmetrically to each. **On the partisan-fairness metrics, the majority map is not a UCP-advantage outlier on any of them** — it sits within the neutral band on three of four, and on the fourth (mean-median) it falls at the NDP-favourable tail, not the UCP tail (p0.99; see §5.4.9). **The minority map is a UCP-advantage outlier.** That is measured against neutral plans, which on Alberta's geography give the NDP more than half the seats at a tied vote. In absolute terms the minority is closer to an even split at 50/50 than the majority (46 UCP seats of 89 against 41).

The minority proposal differs from the majority on four measurable non-partisan-bias dimensions: population dispersion (mean absolute deviation 48% wider on the

commission's 2024 tables), Calgary geographic-zone asymmetry (12.2% vs 0.4%), Airdrie community fragmentation (three pieces by the audit's 2 % piece rule, four districts by territory, against two), and boundaries the commission majority objected to (four named, three confirmed as geometric anomalies by the audit; the majority's wider criticism spans 7 configurations across two sections of its report, analysed in this audit's §5.8.2 and §5.9.4). That last count is one-sided: the minority report in turn criticised the majority for deleting or "mangling" rural divisions (final report, p. 356), and the audit's anomaly questions were built from the minority's boundaries (§5.8.3). Three of the four signals hold under every check; the population gap shows on the commission's 2024 tables but not on the 2021 census (Appendix C). A fifth pre-registered dimension — municipal-boundary anchoring — did not survive canonical recomputation: both maps are close to the 2019 map's 75.1% on the same measure (majority 80.0%, minority 71.8%). The failure is documented in full at §5.8.5 rather than quietly removed.

The partisan-bias evidence rests primarily on the **ensemble test** (Mahalanobis Ch1, §5.4.9): *is this map extreme relative to over one million neutral, randomly-drawn Alberta maps?* The minority's joint profile is more extreme than every one of the 1,010,000 neutral plans sampled — beyond the ensemble's entire empirical range (a parametric $\chi^2(4)$ model puts the tail near $p \approx 8.80\times10^{-7}$, about 1 in 1,140,000, but the observed Mahalanobis distance lies past the sampled maximum, so that figure is a model extrapolation, not a measured frequency and not a bound; the sample alone supports p below about 6.9×10^{-4}, the rule-of-three bound 3/n_eff — see Appendix G). A secondary **boundary-choice test** (SZAT Ch2, §5.2.10) — *are the specific lines where the minority drew differently from the majority partisan-neutral?* — returned p = 0.0024 under the original i.i.d.-flip null but **p ≈ 0.19 under a contiguity-respecting block-permutation null** (T1.10b closed 2026-06-12; see `findings/szat_block_permutation.md`). The 2,110 swing-zone VAs cluster into one giant connected component (2,086 VAs), so the i.i.d.-flip null *understated* the variance by 5.79× relative to the methodologically-correct block null. The Ch2 evidence does not survive the contiguity correction and is no longer used in the audit's joint headline. **The headline is Ch1 alone: parametric $p = 8.80\times10^{-7}$ against the canonical neutral ensemble; the parametric value doubled for two channels is $p \approx 1.76\times10^{-6}$ (exploratory — see §1 and §4.3.1 for the exploratory/confirmatory distinction)** (the earlier "2 × min(Ch1, Ch2)" bound applied under different assumptions; the new bound reflects the 2026-07-12 ensemble rerun). The neutral plans have 87 districts and the commission maps 89. The minority's per-metric tails hold on 89-district constrained nulls, and a size-matched joint test is pending (§5.4.9). The earlier "$p \approx 4.61\times10^{-8} \approx 1$ in 22 million" Fisher figure assumed channel independence; it is retired. The main ensemble's seed derives from a public drand round (5,500,000, emitted in October 2025), with its salt fixed in code on April 27, 2026; the evidence for that date is the git record, rewritten on May 12 (§5.4.9). The seeds set under OSF s58a6 (its SZAT seed check, and the rerun base seed the 2015 and 2019 ensembles use) and the anchoring ensemble's seed come from a later round, 6,099,592, fetched on May 10, 2026, after the shapefiles arrived (`preregistration/seed_robustness_rerun.md`); all reproduce under the derivation formula s58a6 registers (the anchoring salt is recorded in

`mcmc_anchoring_ensemble.py`, not in the registration). All scripts and data are public; an independent analyst running the same pipeline should recover the same numbers, but no one has yet replicated them.

Channel 3 — neighbour-drain adjacency — is not part of the Bonferroni headline ($p \approx 1.76 \times 10^{-6}$). The drain test (§5.3.5; OSF r3zm7, filed about six hours after the shapefiles arrived) asks, within each map, whether packed districts tend to border closely-won districts. On the canonical Elections Alberta shapefiles, all three maps are anomalously *low* relative to their own label-shuffle nulls: 2019 enacted z = −3.520, majority z = −3.173, minority z = −2.750 (two-tailed $p \leq 0.0002$ for all three). The majority is not singularly anomalous on this metric — the 2019 enacted baseline is the most anomalous of the three, and all three maps sit at the 0th percentile of their respective nulls. r3zm7's Prediction A (drain(majority) > drain(minority) in raw drain-score terms) held, but it holds about 91% of the time under random labels. Its Prediction B (both maps inside the null, $p > 0.05$) failed: all three maps are anomalously low. The narrative that the majority stands out as uniquely anomalous does not survive the three-way comparison: the finding is that every Alberta map examined — including the pre-commission 2019 baseline — produces unusually low neighbour-drain scores relative to an unconstrained label-shuffle null. Full results and interpretation at §5.3.5.

The directional consistency across structural and statistical dimensions is the finding. The audit records what the data show. It does not reach a legal conclusion and does not infer intent (§4.5). The partisan-bias magnitude is sensitive to the vote-attribution method used and should be read as a directional observation, not a point estimate (§1.2, §5.2.2). See §1.1 for the full plain-language summary, §1.2 for modelling-uncertainty caveats, and §6 for the author's verdict on both maps.

Reading guide by question. The monograph has three parts, each answering a different question and each referencing the others:

IF YOU ARE HERE TO ANSWER…	READ	COVERS
Part I — Empirical audit. *Do the two 2026 maps differ in measurable, reproducible ways?*	Abstract, §1.1, §5.1 (population equality), §5.2 (partisan bias), §5.3 (signatures), §5.4 (MCMC ensemble), §5.6 (symmetry counter-test), §5.7 (stress-test grades), §5.8 (geographic coherence)	Core quantitative findings — the empirical redistricting audit.
Part II — Procedural and policy critique. *What does the April 16 legislative pivot mean; how does the commission's methodology compare to Canadian norms; what statutory reforms follow?*	§5.9 (procedural), Appendix F (constitutional framing), `docs/act_amendment_proposal.md` (statutory reform), `findings/cycle_lag_analysis.md` §2 (forward-modelling consequences for commissions)	The Canadian comparative and legal-procedural layer.

IF YOU ARE HERE TO ANSWER...	READ	COVERS
Part III — Data provenance and methodological warnings. *Why can't the audit give single-number point estimates on every metric; what does the missing-shapefile situation do to conclusions; what's the DPG framework?*	§4.1.4 (DPG + sunset clause), §3.3 (cycle-lag robustness + dataset-construction consequences), §5.2.7 (four-measurement-layer reporting), Appendix E (approximate geometry), `findings/cycle_lag_analysis.md` §1 (three-vintage sandwich), `findings/methods_paper_draft.md` (companion methodology paper in draft)	The GIS and data-provenance methodology — the part justifying every qualified finding in Parts I and II.

This monograph is the source. Three shorter pieces can be drawn from it for different audiences: a peer-reviewed audit paper, a methods paper documenting the geometry-reconstruction pipeline (`findings/methods_paper_draft.md`), and a magazine feature. Drafts of each are in progress.

What to believe. Except where noted (RT1 in §5.7, the §5.9.6 sub-claims, the submission archive), every number in this document is reproducible by running a script in `analysis/scripts/` against a dataset in `data/`. Every qualitative claim is anchored in a primary source pinned in `docs/FROZEN_MANIFEST.md`. Where a finding depends on Derived Provisional Geometries (DPG — traced from commission map thumbnails before Elections Alberta provided the official shapefiles on 2026-05-06), the dependency is disclosed via the §4.1.4 sunset clause which binds the audit to re-run the finding within two weeks of official shapefile release.

Abstract

Alberta's 2025–26 Electoral Boundaries Commission reported two 89-seat maps on March 23, 2026 (tabled in the Assembly March 26, Sessional Paper 436/2025-26), which the Legislative Assembly set aside by Government Motion 37 (introduced April 16, passed April 21, 2026). This audit evaluates both proposals against the 2019 baseline using a multi-method structural framework and Monte Carlo ensemble analysis. Four non-partisan structural signals show consistent findings: the audit identifies structural divergence on population dispersion (minority 48% wider), Calgary zone asymmetry (12.2% vs 0.4%), Airdrie fragmentation (4 vs 2 districts by territory; 3 vs 2 by the 2 % piece rule)[1], and boundaries the commission majority objected to (four named, three confirmed as geometric anomalies; the majority's criticism spans 7 configurations across §5.8.2 and §5.9.4; the minority report's criticisms of the majority map are not counted this way). Three of the four hold under every check; the population gap shows on the commission's 2024 tables but not on the 2021 census (Appendix C). A fifth pre-registered dimension — municipal-boundary anchoring — did not survive canonical recomputation (both maps close to the 2019 map's 75.1%). Full reconciliation in §5.8.5.[3] The joint outlier profile is more extreme than all 1,010,000 plans in the canonical ensemble — beyond its empirical range (a parametric Mahalanobis $\chi^2(4)$ extrapolation past the sampled maximum gives $p \approx 8.80\times10^{-7}$, a model estimate, not a measured frequency; the sample alone supports p below about 6.9×10^{-4} — see Appendix G). The ensemble's plans have 87 districts and the commission maps 89; a size-matched joint test is pending (§5.4.9). Under 2023 votes both maps'

Efficiency Gaps are below the 7% figure used in US litigation (*Whitford*; never judicially adopted); under 2015 votes both exceed it, as do most neutral plans. The audit records what public data show. It does not reach a legal conclusion. Primary statistics are exploratory and reproducible. OSF r3zm7 (Channel 3; AsPredicted #289,451) and qsgy8 (a Phase 2 comparison and four tripwires for the November map) were filed on 2026-05-06, about six hours after the shapefiles arrived; qsgy8's tripwires are reported beside the November verdict, which `preregistration/november_2026_scoring_spec.md` (June 2026) decides. The other OSF entries (w2s8k with r3zm7; 6pt83 and 9wp5y that evening; yvc7g and s58a6 on 2026-05-10; he53s and u47bq in July) were also filed after the shapefiles arrived — see §4.3.3 and §5.3.1 for the verified-content disclosure (corrected 2026-06-12 per T1.7 R2 Ref #4); each registers its own test or protocol (w2s8k the DPG geometry validation, 6pt83 the SZAT bootstrap after its first results were known, 9wp5y the 17-test checklist, yvc7g the inter-map permutation test, s58a6 robustness reruns, he53s the Forest-ReCom check, u47bq the process scorecard), and none is cited as evidence of *prospective* pre-registration for the Ch1 + Ch2 framework.

Preface — scope, shapefile status, and intended venue

Shapefile status (updated 2026-05-06). Elections Alberta provided the 2026 official shapefile package on request, and the canonical polygon files were received by the audit on 2026-05-06. The §4.1.4 sunset clause has been triggered and partially fulfilled: the 2026-proposal-shapefile trigger fired 2026-05-06 and the canonical ensemble re-run is complete (rerun clean 2026-07-12; C9, C10). The November 2026 trigger, for the advisory panel's map delivered to the committee on October 22, 2026, remains pending. Authoritative canonical results are documented in §5.4.9 and `findings/post_audit_recompute_deltas.md`. The DPG-substrate runs documented in §5.4.1–§5.4.8 are preserved as the historical record of the pre-shapefile analysis.

The canonical ensemble is 1,010,000 neutral ReCom plans of 87 districts each, across 4 chains × 252,500 steps, base seed `get_canonical_seed("mcmc_ensemble_250k") = 1432864451` (corrected 2026-07-13: the salt was previously mis-cited as "lunty-bootstrap"; the seed value itself was always correct — `get_canonical_seed("mcmc_ensemble_250k")` reproduces 1432864451 exactly, `get_canonical_seed("lunty-bootstrap")` does not). The official Elections Alberta shapefiles (`ea_majority_2026_eds.gpkg`, `ea_minority_2026_eds.gpkg`, EPSG:3400, 89 EDs each) are used only to score the two commission maps against those plans. Results not dependent on the 2026 shapefiles remain unchanged: population equality in §5.1 (uses the commission's own per-ED population tables) and the public-submission audit in §5.9.4 (commission's own submission archive).

Intended venue and distribution. The paper is prepared as a public-interest audit. Primary distribution targets are the project's public GitHub repository and a Canadian public-policy venue (*Alberta Views*-length feature and/or an SSRN / OSF preprint). Re-routing to a peer-

reviewed journal (*Canadian Journal of Political Science*, *Canadian Public Policy*, *Election Law Journal*) is welcomed. The paper's structure, framework, and data are designed to make the re-routing straightforward. The methodology, pre-registration (§5.5), and falsifiability gates (§4.1.2) are intended to support review at the standard. A companion methodology paper on the DPG framework is in draft at `findings/methods_paper_draft.md`.

Cover visualization

The cover map (`data/maps/cover_art.png`; script `analysis/scripts/build_cover.py`) renders the minority commission's 2026 proposal as a population-density-weighted vote-share choropleth of Alberta's 4,765 Voting Areas. Each VA polygon is filled with a colour interpolated linearly from NDP-orange (rgb 0.961, 0.510, 0.125; #F58220) to UCP-blue (rgb 0.110, 0.271, 0.514; #1C4583) against each VA's 2023 election-day two-party UCP share (colour scale normalised vmin = 0.35, vmax = 0.75). Fill lightness is modulated by $\log_{10}$ population density: a weight maps [−8.5, −3.5] $\log_{10}$ persons/m² to [0, 1], is raised to the power 0.6 and floored at 0.18, and blends the partisan colour with white, from a pale tint at the sparse end to the saturated colour at the dense end. EDs that no VA centroid falls inside take their vote share from their crosswalk 2019 parent EDs, or failing that from the K = 25 nearest VAs. The minority commission's ED boundaries are overlaid in grey (#718096, linewidth 0.1), and the provincial outline in dark red (#7a1f1f, linewidth 0.2).

The visualization corrects the geographic distortion produced by whole-riding colour fills on standard election maps, where large rural ridings dominate the visual field despite comparatively sparse populations. By saturating colour only where population density is high, the render makes the urban-core concentration of competitive voters visible as a primary feature of Alberta's political geography rather than a small detail lost in a sea of rural blue. This is directly relevant to the audit's structural findings: the boundary choices mattering most — the NE/central Calgary zone, the Airdrie split, the lasso corridor — fall precisely in the high-density zones where the map's partisan signal is strongest.

Author disclosure

Author and audit design: Will Conner, Mount Royal University, BSc Computer Information Systems (4th year student).

Prior and bias self-audit. Going into this project the author held the prior the UCP government's handling of boundary redistribution warranted scrutiny. The methodology is designed to produce the same numbers regardless of the prior. Three cases surfaced findings running against the prior and were retained in the report: (i) under 2019 vote input the minority's efficiency gap falls inside the neutral range, although the minority remains the more UCP-favourable map (§5.2.8; C44); (ii) the majority report's "no public support"

claim holds for three of the five places it names (§5.9.4; C43); (iii) on the 2021 census, all three maps have almost the same mean absolute deviation (2019 map 9.7% of quota, majority 10.1%, minority 10.2%; Appendix C), so the minority's 48% wider spread shows only on the commission's 2024 tables. Separately, two registered predictions failed: qsgy8 Part A (registered 2026-05-06) predicted the minority map would be better for the NDP and more equal in population, and both missed (§4.3.3). Full bias self-audit at `findings/partisan_bias_summary.md`.

AI use disclosure. Four AI tools were used: **Claude** (Anthropic), **Gemini** (Google), **Kimi** (Moonshot AI) and **Codex** (OpenAI). Claude worked in two ways. As a writing and analysis assistant, it drafted and revised text, proposed structure, found inconsistencies across documents and surfaced methodological edge cases (for example, the Vote Anywhere apportionment issue and the pre-registration disclosure requirement). As a coding agent (Claude Code), it wrote and ran scripts at the author's direction, among them ensemble runs, scoring, figures and the website build; it fetched public documents (legislation, commission reports, Hansard, OSF records), translated the website and committed its changes, which are in the repository's history. Gemini, through the Gemini CLI and the Antigravity IDE (April 23 to May 8, 2026), evaluated the paper, red-teamed the audit, audited the code and wrote some code fixes (April 23–26). Kimi audited the code on April 27, 2026. Codex checked the literature review's citations (May 6, 2026). Amendment 6 records the evidence for each. One part of the analysis rests directly on AI output: the public-input labels behind §5.9.4.6 and §5.9.4.7 come from a Claude model, and a Claude vision model inspected the commission's map images (§5.8.1). The author directed the work, made the methodological decisions and approves what is published. Numbers and quotations were checked against primary sources and script outputs; many of those checks were run by Claude sessions at the author's direction, and their reports are in `analysis/review/`.

No commercial tools. No GIS desktop software (QGIS, ArcGIS) and no commercial election-analytics platforms were used. R 4.6 was used for one cross-validation script (`analysis/scripts/redist_crossvalidation.R`) using the Harvard `redist` package (SMC sampler; McCartan and Imai 2023) to provide algorithm-independent corroboration of the Python GerryChain ReCom headline finding (§5.4.9). No other R packages were used. Stata and SPSS were not used.

No paid data. All inputs are public. Every number in this audit is reproducible by running a script in `analysis/scripts/` against a dataset in `data/`.

Integrity tools. Falsifiability gates G0–G5 are built into the pipeline. Bias self-audit: `findings/partisan_bias_summary.md`. Uncertainty analysis: `analysis/methodology/shapefile_uncertainty_analysis.md`.

Computational stack:

- **Python 3.14** on Windows 11 (package versions pinned in `requirements.txt`)
- **pandas 2.x** — §5.1 population equality, §5.2 vote attribution

- **numpy** — numerical computation
- **openpyxl** — parsing the 2023 Statement of Vote Excel workbook (87 sheets, 1,973 poll records)
- **geopandas + pyogrio** — spatial operations for population aggregation and ED-to-CSD overlay; run on the official 2026 shapefiles since 2026-05-06
- **shapely + pyproj** — polygon topology and projection, NAD83 / Alberta 10-TM (Forest), EPSG:3400 (the pipeline default; corrected 2026-06-12 per T1.7 R2 Ref #10 from the earlier mislabel "Alberta 3TM, EPSG:3776" — see `analysis/methodology/canonical_shapefile_log.md` for the full CRS reconciliation)
- **osmnx** — OSM road network extraction, prepared for Phase 4D fallback
- **gerrychain** — MCMC ensemble generation; canonical 1,010,000-plan run (4 chains × 252,500 steps) against official EA shapefiles (§5.4.9); DPG-substrate development runs of 250k–2,000,000 samples documented in §5.4.1–§5.4.8
- **pdfplumber** — PDF table extraction for commission report and Appendix E parsing
- **geopy + rapidfuzz** — geocoding and fuzzy-string matching
- **R 4.6** — cross-validation only; `redist` package (SMC sampler, Harvard); one script (§5.4.9)
- **git, GitHub CLI** — version control; public repository Ixby/alberta-electoral-boundaries-audit

1. Introduction

Contribution. (d) The primary contribution is the first systematic computational audit of an Alberta provincial electoral boundary commission's output, evaluated against established Canadian independent-commission practice and statutory norms. The audit is situated within Canadian political-science and legal frameworks: the *Saskatchewan Reference*'s "effective representation" standard, the Courtney–Pal lineage of scholarship on boundary-commission discretion, the statutory mandate of Alberta's *Electoral Boundaries Commission Act*, and the institutional context of the 2022 Federal Electoral Boundaries Commission for Alberta, Quebec 2010–11, and other provincial cycles. This Canadian-institutional framing distinguishes the audit from US-focused partisan-gerrymandering measurement. It asks whether one faction's boundary choices within a Canadian independent commission exceed the discretion space Canadian law and practice establish.

(a)–(c) Supporting contributions. The audit achieves this primary finding through three methodological supports: **(a)** a falsifiability-gated ensemble-comparison framework whose seeds derive from a public randomness-beacon round, with salts fixed in code on April 27, 2026 (dated by the git record); **(b)** a record of which tests were written down before their

results and which after (§4.3.3); the tests for the November map are registered ahead of it (OSF qsgy8 Part B, u47bq; `preregistration/november_2026_scoring_spec.md`); and **(c)** complete data provenance documentation and reproducible code (all scripts checked in, all data sources listed with access dates, with a 1,010,000-plan canonical ensemble enabling third-party replication).

Specifics. The audit evaluates Alberta's 2025–26 Electoral Boundaries Commission's two final proposals (majority and minority reports, dated March 23, 2026 and tabled March 26) by constructing a 1,010,000-plan neutral ensemble of 87 contiguous districts, balanced to ±12.5% at the proposal step (the Act allows ±25%; community of interest is not modelled), and comparing each real map against the ensemble statistics. It finds the minority proposal diverges from the majority on measurable structural dimensions across multiple correlated dimensions (not all independent — see dependence disclosure in §4.3.1); the directional pattern of divergence is stable across vote inputs (2015, 2019, 2023) and stress tests; the divergence's direction favours the governing party under all three elections and the uniform-swing polling probe (the crosswalk probe points the other way by one seat); and the underlying rationales offered by the minority commissioners fail falsifiability checks against cleaner legal alternatives (documented in §5.9.4). The paper documents every source, script, and computational step so future users — academic auditors, policy analysts, courts, or future commissions — can run the same pipeline on new commission output.

Case context and procedural pivot. Alberta's Electoral Boundaries Commission delivered two final reports on March 23, 2026: a majority report and a minority report proposing incompatible 89-seat maps. Weeks later the Alberta Legislative Assembly set both reports aside: Government Motion 37 (introduced April 16, passed April 21, 2026) established a Select Special Committee of six MLAs (four UCP, two NDP) to oversee an independent review. The committee engaged an independent advisory panel, which drew a 91-seat map and delivered its report on October 22, 2026. On October 28 the committee voted 3–2 to end its review without observations (committee transcript, pp. CEB-67 and CEB-73); the report had to go to the Assembly by November 2. This procedural pivot — setting the commission's reports aside and moving the remaining work to a legislature-selected committee and its advisory panel mid-cycle — is evaluated in §5.9 against Canadian comparators and positions the audit's findings within a broader questions about electoral commission independence and public trust.

Exploratory vs. confirmatory status. The audit's statistical tests fall into two categories readers should distinguish. The primary ensemble-based tests — Ch1 (Mahalanobis joint-tail) and Ch2 (SZAT bootstrap, exploratory only; the standard-permutation result, p=0.0024, does not survive a block-permutation null correcting for spatial autocorrelation: p≈0.19, see §5.2.10) — are **exploratory**: computational seeds derive from a public drand League of Entropy round (5,500,000, emitted in October 2025), with salts fixed in code on April 27, 2026, before the official shapefiles arrived; the evidence for that date is the git record, rewritten on May 12, so it is not third-party evidence. The specific test names and combination method were not filed in any OSF pre-registration document before

execution. The earlier Fisher combination of Ch1 and Ch2 ($T = 39.87$, $p = 4.61\times10^{-8}$) is retired — it assumed channel independence that the two channels do not have and relied on a Ch2 result that does not survive the appropriate spatial null. The operative joint headline is **$p \approx 1.76\times10^{-6}$**, the parametric Ch1 value doubled for the two channels examined (a model extrapolation; the sample alone supports p below about 6.9×10^{-4}). These findings are reproducible, but they should be treated as requiring independent replication before confirmatory weight is assigned. The Ch3 neighbour-drain test (OSF r3zm7) was filed about six hours after the shapefiles arrived and reports the official-geometry counts it predicts from, so it is exploratory too. The tests for the November 2026 map are registered ahead of it: `preregistration/november_2026_scoring_spec.md` (June 2026) decides the verdict, and qsgy8's tripwires are reported beside it. The four surviving non-partisan-bias signals in §1.1 (population equality, Calgary zone gap, Airdrie fragmentation, the boundaries the commission majority flagged) do not depend on the statistical tests at all. They derive from the commission's own published tables, maps, and record, and their evidentiary status is independent of the pre-registration question. (Municipal anchoring, a fifth pre-registered dimension, did not survive canonical recomputation — see §5.8.5.)

1.1 HEADLINE FINDINGS IN PLAIN LANGUAGE

Before the technical caveats below, the audit's structural findings summarise cleanly. Using the same methodology applied symmetrically to all three maps:

- The **minority 2026 proposal spreads population more unevenly** across districts than the majority proposal (Mean absolute deviation from provincial average: 4,707 versus 3,180; corrected 2026-07-08: previously labelled Median Absolute Deviation — the 3,180/4,707 pair is the mean absolute deviation per `findings/population_equality.md` Table A1, which lists Median population as a separate row) — a 48 % wider dispersion.
- The **minority map's Calgary districts** show a 12.2 % geographic-zone asymmetry (north, east and central districts larger; south and west smaller) versus 0.4 % on the majority map; recoded strictly to the stated dividing line, or by 2023 winner, the minority's gap is 7.7 % (§5.1.2).
- The **minority map divides the City of Airdrie among more electoral divisions than the majority's two**: three pieces by the audit's 2 % piece rule (the majority report counts four, p. 62). On 2021 census areas over the official boundaries (`data/outputs/airdrie_split_shares_2026-10-31.json`), the minority's Airdrie-East holds 54.7 % of the city's residents (and is 89.6 % Airdrie); the rest goes mainly to Calgary-Airdrie (24.0 %) and Calgary-Foothills-Airdrie West (20.9 %), where Calgary residents outnumber Airdrie's. The majority divides the city roughly in half between Airdrie-East (49.4 %) and Airdrie-West (50.6 %), both Airdrie-majority divisions. Calgary-Foothills-Airdrie West's anchoring on Airdrie's gazetted city limit, reported as 0 % from pre-canonical geometry, is 10.8 % of its perimeter on the official boundaries (5.9 of 54.7 km, by the same 500 m snap method; 4.15 km lies within 20 m of the limit; `data/outputs/airdrie_city_limit_anchoring_2026-10-31.csv`). See `findings/airdrie_highway_pretext.md` for the pre-canonical per-ED measurement;

its refutation of a Highway Anchoring Defense at this carve rested on those perimeters and is not reproduced on the official boundaries, where the two Calgary-edge Airdrie districts follow major highways for 76–81 % of their perimeters.

- A fifth pre-registered structural dimension — municipal-boundary anchoring against Statistics Canada CSD edges — did not survive canonical-geometry recomputation: both 2026 maps are close to the 2019 map's 75.1 % on the same measure (minority 71.8 %, majority 80.0 %, computed by `score_anchoring.py` under the pre-registered *contiguous ≥ 1 km run-length* filter — the filter was flagged missing 2026-06-12 per T1.7 Referee #10 D8 and landed the same day (T4.10-anchor); the values cited here are the filtered result, rerun 2026-07-12, not the earlier permissive per-segment reading). Since municipal anchoring is no longer load-bearing (the partisan headline rests on the MCMC ensemble; the structural dimensions compare the two maps), this dimension does not affect the audit's primary findings either way. The earlier DPG-derived 14.5 % / 71.0 % / 4.9× figures cited during the audit's pre-shapefile phase did not carry forward to recomputation against official Elections Alberta shapefiles. Full reconciliation in §5.8.5.[3]
- **Four minority boundaries** were flagged by the commission majority, and the audit confirmed three as geometric anomalies (Rocky Mountain House–Banff Park extension; Calgary-Nolan Hill–Cochrane lasso; Olds-Three Hills-Didsbury → N Airdrie community capture). The majority flagged none on its own map; the minority report, for its part, criticised the majority for deleting or "mangling" rural divisions (final report, p. 356).
- Checked against the **minority's own published rationales**, six contested configurations split: two fail on population arithmetic (a cleaner statute-compliant option existed), two are partly supported, one was not tested on its stated grounds, and one has no stated rationale (§5.9.6). (A seventh configuration — Lethbridge / Taber-Warner federal-boundary match — was previously listed but has been removed: the minority report does not in fact make the federal-boundary claim, and the methodology check at `analysis/methodology/reference/lethbridge_federal_boundary_check.md` could not locate any underlying source.)

The four surviving non-partisan-bias signals all point in the same direction. Three hold under every check in §1.2 below; the population gap shows on the commission's 2024 tables but not on the 2021 census (Appendix C). (The fifth, municipal anchoring, did not survive canonical recomputation — see §5.8.5.[3]) The partisan-bias signal (the extent to which the maps would produce different seat counts from the same votes) is reported in the abstract as a two-measurement disagreement; §1.2 explains the caveats constraining the magnitude claim.

The headline rests on Ch1 (Mahalanobis joint tail). The ensemble test (Mahalanobis Ch1, §5.4.9) asks: *is this map extreme relative to over one million neutral, randomly-drawn Alberta maps?* The minority's joint distance is more extreme than all 1.01M plans sampled — beyond the ensemble's empirical range; a parametric $\chi^2(4)$ extrapolation gives $p \approx 8.80 \times 10^{-7} \approx$ about 1 in 1,140,000, but because the observed distance lies past the sampled maximum this is a model extrapolation, not a measured frequency or a bound; the sample alone supports p below

about 6.9×10^{-4} (see Appendix G). A secondary SZAT boundary-choice test (Ch2, §5.2.10) returned p = 0.0024 under the original i.i.d.-flip null but **does not survive a contiguity-respecting block-permutation null** (block-permuted p ≈ 0.19; T1.10b closed 2026-06-12 per T1.7 R1 Ref #1; see `findings/szat_block_permutation.md`). The audit therefore reports Ch1 as the load-bearing partisan-bias finding; the parametric value doubled for two channels, **$p \approx 1.76\times10^{-6}$** (updated 2026-07-12 per C10), reflects the cleaned ensemble rerun. The earlier "$p \approx 4.61\times10^{-8} \approx 1$ in 22 million" Fisher figure assumed channel independence and overstated the joint significance (§4.3.3 explains the revision).

1.2 Modelling-uncertainty caveats

Three modelling-uncertainty tests bear on the partisan-bias magnitude claim while leaving the structural findings in §1.1 intact — one now confirms the magnitude rather than narrowing it (item 1, updated 2026-07-12; see DOCUMENTED CORRECTIONS C11), item 2 no longer narrows it after the sign correction, and item 3 narrows it. These are reported up-front for transparency. The underlying methodology is in `analysis/review/design_critique.md`, `analysis/scripts/monte_carlo_ci.py` (item 1's retired predecessor check), and `findings/maup_attribution_canonical.md` (item 1's current check).

1. Attribution-method sensitivity confirms the magnitude, replacing the retired blend-model Monte Carlo check (DOCUMENTED CORRECTIONS C11). The blend-model Monte Carlo interval formerly reported here (N=2,000 samples varying urban weight, rural baseline, per-hybrid jitter; mean −1.22 pp, CI [−3.04, +0.76] pp crossing zero) quantified parameter uncertainty in the v0.2 blend model, retired 2026-05-18 in favour of Phase 4C's exact VA-level spatial attribution (§5.2.7; no estimation or blending is applied). `monte_carlo_ci.py` has been unable to run since that retirement (its import of the blend model's `estimate_2026` function broke when that function was removed) and the interval could not be reproduced. The applicable robustness question for Phase 4C's exact figures is sensitivity to attribution *method*, not blend *parameters*: centroid-in-polygon (the audit's method) and population-weighted MAUP — the most rigorous attribution available without external polling-station geocoding — agree to within 0.1 pp on every partisan-bias metric on both maps; the minority's EG varies by at most 0.07 pp across all three tested methods (centroid +4.02%, area-weighted +4.00%, population-weighted +3.95%). The Phase 4C headline +3.96% is the centroid figure computed on voting-area votes truncated to whole numbers (`packing_cracking_analysis.py`), which lowers it by 0.06 pp. Full numbers in `findings/maup_attribution_canonical.md`.

2. Declination metric (Warrington 2018) — sign-convention correction landed 2026-06-12 (Amendment 5, Part 9). The implementation at `mcmc_ensemble.py:227` was returning the operand pair in inverted order relative to Warrington 2018, producing values with the wrong sign. The corrected values are: 2019 = +0.045 (p91.33), Majority = −0.027 (p21.85), Minority = **+0.077 (p98.79)** against the canonical 1.01M-plan ensemble. Under the corrected sign, declination *agrees* with EG, mean-median, and seats@50/50 on the UCP-favoured tail

— four of four partisan-bias metrics in the same direction. The prior "disagreement" reading in earlier drafts of this report was a code-side artefact; see Amendment 5, Part 9 in `findings/pre_registration_amendment_log.md`, and Appendix D.3 for the verification and chain-CSV migration.

3. 2019 cross-election check (corrected 2026-06-13 per T1.7 R2 S4). Under v0_7 partial-coverage attribution, 2019 vote totals produced Majority EG +0.30% / Minority EG +0.90% — an apparent direction-flip relative to the 2023 reading. An earlier v0_8-based run (`cross_election_v8_full.csv`, 2026-04-25) claimed "neither individual map's EG sign flips under 2019"; that claim does not hold. **Under canonical Option C (area-proportional VA attribution on the official 4,765-VA substrate, 100k-plan ReCom ensemble, seed 3562959107; §5.2.8):** 2019 EG values are Majority −1.32% (p48.3) and Minority −0.49% (p70.4) — both negative, meaning both maps are NDP-favourable under 2019 votes. The EG sign DOES flip across elections; the earlier v0_8 no-flip claim was an attribution artefact. The inter-map *asymmetry* direction does not reverse under 2019: the minority stays the more UCP-favourable map, by 0.83 pp under 2019 against 3.92 pp under 2023 (majority − minority = −0.83 and −3.92 pp). What changes is the minority's placement: under 2019 votes its EG falls inside the normal range (p70.4), while its mean-median (p96.1) and seats@50/50 (p98.5) stay in the UCP tail. The 2019 EG figures are in §5.2.8; the other two placements come from the same 2019 run. The canonical Option C finding — that EG flips for both maps under 2019 — does not alter the audit's primary claim, which rests on the 2023-context canonical ensemble (the appropriate reference for a 2026 map): MM p99.97, Declination p98.79, s50 p99.99, joint D^2=33.64 p=8.80×10^{-7}.

What survives these tests unchanged: - §5.1.1 population distribution variance (CSV-sourced, election-independent): minority MAD is 48% wider than majority on the commission's 2024 tables; on the 2021 census the three maps are almost level (Appendix C). - §5.1.2 Calgary geographic-zone gap: minority 7.7–12.2%; majority 0.36–0.39%. Not vote-based. - §5.8.2 visual spatial anomalies: of the four minority boundaries the commission majority named, 3 confirmed as anomalies on published maps. - §5.8.4 community splits: Airdrie 4 vs 2 by territory (3 vs 2 by the 2 % piece rule), Cochrane merged vs intact, Chestermere partial split vs intact. - §5.9 procedural concerns: the Assembly's replacement of the commission process with a legislature-selected committee and its advisory panel, qualitative.

What is narrowed: - The "minority gives UCP 2 more seats in a tied election" line. Phase 4C's exact seats@50/50 count is minority 43 vs majority 48 under 2023 votes — a 5-seat gap, not the blend-model-era 2-seat figure this bullet originally narrowed. The *direction* of the gap is not invariant to vote input: it holds under 2023 votes and the canonical uniform-swing probe on April 2026 338Canada polling, but the crosswalk-reallocation probe on the same polling data finds a 1-seat NDP advantage on the minority instead — see §5.2.3 (C7) for the probe-level reconciliation. A structural-invariance claim was not supported by the historical stability test and is not made. - Under Amendment 5, Part 9 (declination sign correction, 2026-06-12) the four partisan-bias metrics agree on direction; the earlier "five of six" framing was an artefact of the now-fixed sign error. The honest precision is

"directionally consistent across six tested dimensions, no metric pointing the opposite way once code-side errors are corrected; consistency is across *correlated* dimensions, not statistically independent ones — see Referee #14/#16 findings and the §6 wording fix."

Defensible synthesis. The minority 2026 proposal shows measurable structural differences from the majority in four areas: population distribution (MAD 48% wider), Calgary geographic-zone balance (12.2% gap vs 0.4%, robust across two classification rules), community-of-interest treatment (the minority gives Airdrie one Airdrie-majority district, holding 54.7% of the city, and places most of the rest in two districts where Calgary residents outnumber Airdrie's, against the majority's two Airdrie-majority districts — the same dispersion pattern is visible in Lethbridge and Red Deer per §5.6), and visible boundary shape (three confirmed anomalies). None of these depend on vote data.

A fifth dimension is the rationale check on six contested minority redraws (after the Lethbridge / Taber-Warner federal-boundary claim was dropped from the draft — see methodology check `analysis/methodology/reference/lethbridge_federal_boundary_check.md`, which establishes the minority report does not in fact make the federal-boundary claim attributed to it). Two (Airdrie, Olds-Three Hills-Didsbury) had cleaner options satisfying the statutory population and area limits. Two (Cochrane, Red Deer-Sylvan Lake) are partly supported by commuting and school data. Rocky Mountain House-Banff Park was not tested on its stated grounds. St. Albert-Sturgeon, once read as constraint-forced, is split three ways by the minority and two by the majority, and has no stated rationale to test (see §5.9.6 and `analysis/methodology/reference/minority_rationales_validation.md`).

The partisan-bias consequences are directionally UCP-favorable for the minority under 2023 vote attribution, stable to within 0.07 pp across three independent attribution methods (§5.2.7; `findings/maup_attribution_canonical.md`), outlier-flagged at p99.97 on mean-median (UCP-tail) and at **p98.79 on declination (UCP-tail; sign convention corrected 2026-06-12, see Amendment 5, Part 9)** against the 1,010,000-plan canonical ReCom neutral ensemble on official Elections Alberta shapefiles (see §5.4). Under 2019 vote attribution the direction holds but weakens: the minority's lead shrinks to 0.83 pp and its EG falls inside the normal range (p70.4). Under April 2026 338Canada polling, the crosswalk-reallocation probe finds a 1-seat NDP advantage on the minority, but the canonical uniform-swing probe (applied to Phase 4C per-ED results) finds the majority still gives NDP more seats — see §5.2.3 for the probe-level reconciliation (C7). The core claim is the minority has more structural irregularities and more rationale failures than the majority. A specific partisan-seat-shift magnitude is less defensible and sensitive to election baseline. The procedural concern about the April 16 government action stands separately from the partisan-math questions.

Methodological scope. This paper applies a symmetric, falsifiability-gated framework to both 2026 proposals and the 2019 baseline, producing reproducible estimates of population equality, partisan bias, geographic coherence, and procedural fairness. It registers the test battery for a third map — the advisory panel's 91-seat map, delivered to the committee on

October 22, 2026 — before that map existed, so the audit can be replayed against new evidence rather than reinterpreted after the fact. It documents the data-provenance caveats of the period before the 2026 shapefiles were provided, leaving explicit placeholders for the checks remaining pending.

Scope. The paper does not reach a legal conclusion. It is evidentiary: it records what the public data show under identical methodology applied to all three maps, so any interested party — court, legislator, commissioner, journalist, academic — can repeat the computations, challenge the inputs, and reach their own judgments. The court-ready interpretation is deferred to §8 (Conclusion) and Appendix F (Legal Interpretive Note), drawing on Pal's (2015) analysis of boundary-commission discretion and electoral-district design.

---

2. Background and Prior Work

The analysis rests on four bodies of prior work: US partisan-gerrymandering measurement, Canadian independent-commission practice, population-equality jurisprudence, and computational redistricting methodology.

Institutional context: Canadian commissions versus US state legislatures. The US literature on partisan gerrymandering — including the efficiency gap and the ensemble approaches this audit uses — was developed primarily to detect and litigate intentional partisan manipulation by *partisan mapmakers*: US state legislatures, which draw their own districts without independent commissions and have a structural incentive to engineer outcomes. In the US federal courts, however, partisan-gerrymandering claims have been declared non-justiciable: *Rucho v. Common Cause*, 588 U.S. 684, 139 S. Ct. 2484 (2019) (parallel citation restored 2026-06-12 per T1.7 R2 Ref #9 — round-1 of the Rucho-text remediation mislabeled the S. Ct. cite as a "slip-opinion reporter"; in fact it is West's *Supreme Court Reporter*, a valid parallel cite, and is restored alongside the U.S. Reports cite here), held 5–4 the federal judiciary lacks "judicially discernible and manageable standards" for evaluating partisan-bias claims and therefore cannot adjudicate them. This is an *institutional* holding about justiciability, not a *methodological* holding that partisan-bias metrics need corroboration to be reliable. The *Whitford* plaintiffs lost separately, on *Article III standing* grounds (*Gill v. Whitford*, 585 U.S. 48 (2018) — round-1 conflated this with Rucho's justiciability holding; corrected 2026-06-12 per T1.7 R2 Ref #9). The plaintiffs in the North Carolina case decided with *Rucho* nonetheless presented an ensemble + structural + procedural package like the one this audit deploys (Mattingly et al. and Chen ensembles, direct intent evidence); the Court did not reach the merits. This holding closes the federal courts to efficiency-gap and partisan-symmetry arguments, rendering the US academic literature on these metrics non-actionable in US federal law. The same metrics remain viable in US state constitutional courts (most prominently *League of Women Voters v. Commonwealth*, 178 A.3d 737 (Pa. 2018), where ensemble evidence succeeded).

The *Rucho* holding's relevance to this audit is therefore **not** "metrics need corroboration to be reliable" (the corrected reading 2026-06-12 per T1.7 Referee #9), but rather: in a jurisdiction where boundary maps can be challenged under the Charter (Canada, via s.3 and the *Saskatchewan Reference* effective-representation standard, though partisan asymmetry alone is not a ground — see Appendix F), partisan-bias evidence becomes evidentiarily strongest when it carries direction-of-effect and mechanism-of-effect *both*. The audit's two-lane architecture is motivated by that broader evidentiary practice, not by *Rucho*'s specific holding. This audit therefore deploys a "two-lane" approach (Lane 1: partisan-bias metrics in §5.2; Lane 2: structural and procedural findings in §5.1, §5.3, §5.8, §5.9). Neither lane depends singularly on the other. The audit's findings rest on directional consistency across multiple correlated dimensions rather than on the magnitude of any single metric.

Canadian provincial and federal electoral commissions are constitutionally distinct from US state legislatures. They are typically led by a judicial or similar chair with government- and opposition-nominated members, rather than by partisan legislators, are governed by statutes specifying non-partisan criteria, and operate in a setting where the *Saskatchewan Reference* [1991] 2 SCR 158 standard of "effective representation" rather than strict partisan proportionality frames the legal test. Critically, *Rucho*'s non-justiciability holding governs US federal courts only and does not carry over to Canadian provincial jurisprudence, where the Saskatchewan Reference provides an explicit constitutional standard for assessing boundary-commission output. This institutional distinction is material. In the US context, partisan-bias metrics are evidentiary tools unable to enter federal litigation. In the Canadian context, the same metrics are evidentiary inputs to a constitutional test a court is able to apply. The methodology is agnostic to this institutional distinction. Its inferential weight depends on context, and the context is disclosed here. This matters for how partisan-bias metrics carry inferential weight. In the US context, a high efficiency gap is direct evidence of legislative manipulation by the legislature drawing its own map — but federal courts will not hear such claims. In the Canadian context, the same metric applied to a *minority* faction's commissioners within a nominally independent process carries a different warrant. The inference is not "the legislature manipulated its own map" but "one group of commissioners drew boundaries whose partisan signature departs from what the commission majority drew under the same Act," and a court applying the Saskatchewan Reference standard can weigh this evidence as part of its effective-representation analysis.

Terminology. "Gerrymandering" as used throughout this paper is a political and analytical term with no equivalent legal category in Canadian law. In contrast to US jurisprudence — where partisan gerrymandering is at least a named (if non-justiciable) claim after *Rucho* — Canadian law defines no gerrymandering standard. The applicable legal framework is effective representation under *Charter* s.3, as articulated in the *Saskatchewan Reference*, and statutory compliance with the EBCA. This audit's findings are evidentiary inputs to those constitutional and statutory questions, not to any gerrymandering-specific legal test.

Partisan-bias measurement. Stephanopoulos and McGhee (2015, 2018) introduced the efficiency gap (EG) as a single-number measure of wasted-vote asymmetry and proposed

presumptive thresholds of two seats for congressional plans and 8% for state-house plans; the 7% figure this audit also reports entered US litigation through Jackman's expert analysis in *Whitford* (§5.2.8). McDonald and Best (2015) advanced the mean-median gap as a complementary measure of distributional skew. Gelman and King (1994) formalised seat-vote-curve symmetry as a Bayesian estimator, building on Grofman (1983) and King and Browning (1987). Warrington (2018, 2019) introduced declination and documented EG and declination can disagree on a non-trivial fraction of US-state plans; the Alberta disagreement once reported in §5.2.4 turned out to be a sign error (Amendment 5, Part 9). Katz, King, and Rosenblatt (2020) argue that any valid measure of partisan bias must satisfy symmetry and critique single asymmetric metrics as inadequate; the audit's ensemble measures departure from neutral plans, not from symmetry, and does not claim to meet their criterion. Neither the 7 % nor the 8 % line has been judicially adopted (see §5.2.8).

Natural packing vs engineered packing. Chen and Rodden (2013) argue urban-concentrated parties are systematically disadvantaged by neutrally-drawn maps through packing of their voters into city cores. §5.2.5 of this audit applies the Chen-Rodden framework to Alberta and finds the *direction* prediction transfers but the *mechanism* does not: Alberta's UCP-favourable baseline comes from dispersed rural UCP-winning margins, not from NDP urban packing. This matters for what any 2026 map's partisan bias can legitimately be attributed to.

Canadian redistribution practice. Courtney (2001, 2004) provides the authoritative scholarly treatment of the independent-commission model across Canadian provinces; Courtney (2001) chs. 6–7 map the interplay between population equality and community-of-interest discretion underlying the §5.1 and §5.8 findings in this audit, and chs. 10–11 address public-hearing obligations and the scope of judicial review of commission output. Pal (2015) analyses the intersection of boundary-commission discretion with the Charter s. 3 right to vote, arguing the *Saskatchewan Reference*'s "effective representation" standard leaves commissioners substantial latitude reviewable only at the outer margins — not for partisan preference proximity — and the distinction between legitimate design preference and legally reviewable partiality turns on the same factual record the audit assembles. The discretion-versus-design-choice framework Pal develops is the analytic anchor for the §5.9.3 procedural assessment. The constitutional benchmark, *Reference re Provincial Electoral Boundaries (Saskatchewan)*, [1991] 2 SCR 158, establishes "effective representation" — not strict population parity — as the standard against which boundary-commission output is measured. The Charter s. 3 right to vote developed by *Figueroa v. Canada (Attorney General)*, [2003] 1 SCR 912, and *Frank v. Canada (Attorney General)*, [2019] 1 SCR 3, forms the backdrop without applying directly to redistribution. §5.9.3 compares the April 16, 2026 Alberta pivot against Canadian comparators (Quebec 2010–11, where Bill 132 paused the commission's work before its 2011 map took effect) and positions it against the SCC's April 22, 2026 ruling on the Legault government's 2024 freeze statute.

Constitutional framing: effective representation versus variance tests. The *Saskatchewan Reference* standard establishes "effective representation" as the constitutional benchmark

for electoral boundary commissions, but "effective representation" is not a variance ceiling or population-equity metric. Rather, it is a multi-factor constitutional test — articulated in *Saskatchewan Reference* para. 33 — weighing quantitative factors (population distribution, variance in district population) *alongside* non-quantitative factors (geography, historical boundaries, community of interest, minority representation) as evidence bearing on whether the electoral system serves the *practical* ability of electors to cast a meaningful vote.

The *Saskatchewan Reference* para. 33, delivered by McLachlin J., establishes "relative parity of voting power" must be weighed against permissible deviations for "geography, community history, community interests and minority representation." Critically, the Court did not prescribe a bright-line tolerance for population variance or other quantitative measures. Instead, it requires a holistic assessment in which deviations from strict equality are constitutionally defensible *if justified by the non-quantitative factors*. *Raîche v. Canada (Attorney General)*, 2004 FC 679, applied this standard to the federal Electoral Boundaries Commission for New Brunswick (the "per Kelen J." attribution that appeared in round-1 of the Raîche correction was unverified — possibly Shore J. per T1.7 R2 Ref #8's recollection — and is dropped pending counsel verification of the actual judge name; the holding does not depend on it). The Court did **not** find a Charter s.3 violation — applying *Carter*'s deferential "reasonable commission" standard, the boundary transfer survived the constitutional challenge. The violations the Court found were *statutory*: ss.15(1)(b) and 15(2) of the federal Electoral Boundaries Readjustment Act (failure to give adequate weight to community of interest) and Part VII of the Official Languages Act. The remedy was a referral back to the Commission, not boundaries "struck down" under s.3. Earlier drafts of this report described Raîche as a "s.3 strike-down" with attribution to "Heneghan J."; both attributions were corrected 2026-06-12 per T1.7 Referee #8. The case stands for the proposition that statutory community-of-interest protection can require revisiting boundaries even when the s.3 reasonableness threshold is not crossed — a *weaker* claim than the audit previously made, and one that *strengthens* commission deference under the Charter rather than weakening it. (Raîche is a Federal Court trial-level decision interpreting the federal *Electoral Boundaries Readjustment Act*; it is persuasive authority only — not binding on a challenge to a provincial Alberta map, which would proceed under Alberta's own statutory scheme and *Carter*.)

The Saskatchewan Reference and Raîche suffice for the discretion-review framework. Candidate comparators are *Dixon v. British Columbia* (AG) (1989) 59 DLR (4th) 247 (BCSC), where the court held British Columbia's distribution contrary to s.3 (boundaries not sustained), and *Reference re Electoral Divisions Statutes Amendment Act*, 1993, 1994 ABCA 342. In neither Raîche nor any verified comparator did the court examine partisan asymmetry directly; the constitutional inquiry centred on whether the non-quantitative factors had been weighed. This doctrinal architecture means partisan asymmetry, standing alone, does not trigger a Charter s.3 violation under the Saskatchewan Reference standard — the asymmetry must be paired with either (a) unexplained deviations from population parity unjustified by geography, community of interest, or other permissible factors, or (b)

evidence the non-partisan factors (geography, etc.) have been distorted *in service of* partisan outcomes rather than in service of legitimate statutory purposes.

The audit's quantitative findings (partisan-bias metrics in §5.2, population-variance medians in §5.1, municipal-boundary anchoring in §5.8) are inputs to this constitutional test, not proxies for the test's output. No single metric — nor any linear combination of metrics — constitutes a determination of whether a map meets or fails the constitutional threshold. Since *Canada (Minister of Citizenship and Immigration) v. Vavilov*, 2019 SCC 65, review of statutory interpretation is for reasonableness; with the *Carter* reasonable-commission standard for Charter s.3, both standards leave commissioners a broad "discretion space" encompassing legitimate design preferences, as Pal (2015) argues of commission discretion generally. Earlier drafts of this paragraph (and the parallel paragraph in Appendix F) used the "manifest unreasonableness" vocabulary — corrected 2026-06-12 per T1.7 Referee #12; *Dunsmuir* (2008) collapsed the patently/manifestly-unreasonable distinction into a single reasonableness standard, and *Vavilov* kept it, with correctness as the exception. The boundary between justified discretion and reviewable partiality is defined by whether the non-partisan factors genuinely constrained the choices or were invoked *post hoc* to rationalize a predetermined partisan outcome. The §5.9.3 procedural analysis documents evidence on this point: whether the audit's six-dimensional pattern — partisan asymmetry *coupled with* population-variance distortions not explained by geography or community boundaries, *coupled with* procedural departure from the pattern established by the majority under identical constraints — falls outside the range of reasonable outcomes is a question for a reviewing court.

The distinction between s. 3 of the *Canadian Charter* (the right to vote, which the *Saskatchewan Reference* operationalizes) and §15 (equality rights: equality before and under the law) is material: the audit measures deviations in vote efficiency and partisan bias under neutral simulation, providing factual context for whether a commission's output warrants scrutiny. A court's assessment of whether the commission's process was procedurally sound, or its output's partisan asymmetry beyond the justified margins of discretion, is a separate legal question in which non-metric considerations — geography's constraints, rural-urban representation trade-offs, minority communities' distinct electoral needs — weigh equally with the audit's numbers. This report assembles evidence across six dimensions. A finding six indicators point in the same direction is a statement about the empirical pattern, not a legal conclusion. The §5.9.3 procedural analysis clarifies the extent to which the audit's findings bearing on discretion exceed the outer margins Pal identifies.

Compactness and computational methods. Polsby and Popper (1991) and Reock (1961) supply the two compactness metrics referenced throughout. Barnes and Solomon (2021) document their implementation sensitivity. DeFord, Duchin, and Solomon (2021) introduce the ReCom MCMC family used for the neutral-ensemble baseline in §5.4. Cannon, Goldbloom-Helzner, Gupta, Matthews, and Suwal (2023) introduce the short-bursts hill-climbing procedure for exploring biased-but-legal maps. This audit applies their method in §5.4.8 to test empirically whether a non-neutral procedure can reach the minority's seats@50/50

reading under EBCA constraints. Herschlag, Ravier, and Mattingly (2020) demonstrate the ensemble-comparison methodology the Alberta audit applies here. Altman and McDonald (2011) present BARD, open-source software for building and comparing redistricting plans; the consistency-across-dimensions framing in §6.2 is this paper's own, not theirs. Fifield, Imai, Kawahara, and Kenny (2020) discuss the empirical-validation requirements for redistricting simulation results.

Pre-registration and evidentiary discipline. Nosek et al. (2018) and Munafò et al. (2017) codify the pre-registration discipline the audit's November 2026 test protocol follows. American Statistical Association (2016, 2019) statements on p-values and graded evidence guide the audit's reporting of directional findings at sub-threshold magnitude. These disciplines matter because the paper's central claim — six dimensions pointing in the same direction, with three of the four partisan-bias metrics above the pre-registered p95 threshold (MM p99.97, declination p98.79, seats@50/50 p99.99) and EG sub-threshold at p94.54 — is inferentially valid only under pre-registered test selection and reported-versus-hidden-test symmetry. (Note: the pre-correction formulation read "none individually at classical 95% significance"; the sign correction of Amendment 5, Part 9 moved declination from the sub-threshold NDP tail to the UCP-favoured p98.79 reading; corrected per T1.7 R2 Ref #5 2026-06-12.)

The audit's methods map onto this literature as follows: B2–B6 (§5.2.1) implement Stephanopoulos-McGhee, McDonald-Best, Gelman-King (and the broader Grofman, King and Browning partisan-symmetry foundation), and Warrington directly; §5.4 implements DeFord-Duchin-Solomon ReCom against a 1,010,000-plan neutral ensemble (4 chains × 252,500 steps); §5.2.5 validates Chen-Rodden for Alberta; §5.9.3 positions the procedural finding against Courtney's Canadian comparator sample (Courtney 2001, chs. 3–4) and Pal's (2015) discretion framework. Where the Alberta context departs from US or Canadian prior work, the departures are documented rather than elided.

---

3. Data

This section consolidates the audit's data-provenance disclosures — primary sources, their `docs/FROZEN_MANIFEST.md` anchor dates, known coverage caveats, and robustness to cycle-lag. All downstream analyses in §5 inherit from the sources listed here. Deeper provenance notes (including the Plan B population-basis cross-check and the 2021-census-direct legal-baseline reconstruction) are in Appendices C and E.

3.1 Primary data sources

3.2 Coverage caveats

The following coverage gaps constrain the audit's scope. Each is disclosed rather than papered over.

1. **2026 polygon shapefiles released; formal request answered.** Elections Alberta's GIS page did not carry 2026 ED polygons at the time of the audit's initial scope definition (accessed 2026-04-22). A formal written request for the 2026 boundary shapefiles was filed with Elections Alberta, which provided them on 2026-05-06. Elections Alberta GIS

staff confirmed on 2026-05-19 (personal correspondence) that those files are final for the commission maps. The canonical shapefiles are now the basis for all spatial analysis in this audit (`data/shapefiles/canonical/`); all results in §5 inherit from this source. **DPG era (historical, now superseded).** Prior to the 2026-05-06 release, Derived Provisional Geometries (DPGs) were constructed from the commission's report text and Appendix E boundary descriptions; methodology documented in `archive/provisional_geometries/approximate_shape_analysis.md` and `findings/methods_paper_draft.md`. Three iterative refinement passes reduced positional error on Tier A/B boundaries to ≤1 km (mean shift 97 m after v1; residual voter-assignment impact: 1,012 votes across 4 VAs, approximately 0.06% of 2023 valid votes). All DPG-era findings have been recomputed from canonical shapefiles. Per the DPG sunset clause in `analysis/methodology/canonical_shapefile_log.md`, DPG results are archived and no longer the primary analysis basis.

2. **Majority-proposal map imagery (resolved).** Early bundles held only the majority's Calgary map. All eight Appendix A panels have since been extracted and inspected (§5.8.1), and the official shapefiles cover the whole province. The remaining limit is that the anomaly questions were built from the minority's boundaries (§5.8.3).
3. **About 93 public submissions (6.9%) could not be machine-parsed.** Their PDFs are image-only scans lacking a text layer. The submission-archive verification (§5.9.4) rests on identified counter-examples in the 1,252 parseable submissions rather than exhaustive enumeration of all 1,345 (final report, p. 14).
4. **Third-party vote allocation: B2 (EG) is sensitive to the trailing-party rule. B3 (mean-median) is not.** The 2023 Alberta statement of vote includes 58,611 votes cast for parties other than NDP or UCP (3.32% of valid votes) across 80 of 87 existing EDs (summed from the candidate columns of `data/raw/2023_results.xlsx`). The audit's primary analysis excludes these votes (Rule A: drop, converting all margins to NDP/UCP two-party share). Two alternative allocations were tested symmetrically via `analysis/scripts/third_party_sensitivity.py` (2026-05-09, on the retired blend model, C5). Rule B (pro-rate other votes to NDP/UCP in proportion to observed two-party shares) shifts the minority-majority EG asymmetry by 0.02 pp and leaves the direction unchanged (minority −1.87%, majority −0.44%, delta −1.43 pp). Rule C (assign all other votes to the trailing party in each district) reverses the EG direction for *both* maps: minority EG +7.41%, majority +4.16% (positive = UCP-favourable, C13). The mechanical reason: in NDP-held seats won by fewer votes than the third parties took, the other votes go to UCP as the trailing party and hand it the seat, so every NDP vote there becomes a wasted vote; this outweighs the UCP votes the rule adds as losing votes in the NDP seats that hold, flipping the EG sign. The minority map, on which the rule takes more seats from the NDP (38 to 32, against 38 to 35 on the majority), flips further (+3.25 pp gap, reversed direction). B3 (mean-median) holds its direction under all three rules. B6 (declination) follows EG and reverses under Rule C. The paper reports Rule A as the primary metric and Rule C as a deliberate falsification probe. The Ch1 (Mahalanobis joint

tail) and Ch2 (SZAT bootstrap EG) statistics are computed from the same Rule A two-party shares and were not recomputed under Rules B or C.

5. **Election-day votes are the only geographically attributable vote type.** Elections Alberta's published results assign a specific Voting Area number to each election-day polling station. Advance, mobile, and special ballot results are reported at the electoral district level only. EA does not record the home VA of an advance voter in any published data product. In the 2023 Alberta general election, 381,932 NDP votes were cast on election day (geographically attributable to specific VAs) and 395,472 NDP votes were cast advance, mobile, or special (carrying no VA-level geographic identifier). All VA-level vote attribution in this audit uses election-day votes only, via `analysis/scripts/build_canonical_va_votes.py`. No advance votes are redistributed or spatially smeared to VAs by assumption. The election-day share (49.1% of NDP votes; 52.5% of all two-party votes, 896,644 of 1,706,304) is a structural property of EA's result-reporting system — not a modelling choice — and represents the actual geographic granularity available to any analyst working from EA's published data. Election-day voters were also more UCP than the electorate as a whole. UCP took 57.4% of the election-day two-party vote (514,712 of 896,644), against 54.4% of all two-party votes (928,900 of 1,706,304). Seat counts on this substrate are therefore not actual seats. On the 2019 map the substrate gives NDP 30 / UCP 57; the actual 2023 result was 38 / 49 (§5.2.1). Seats at 50/50 and the mean-median gap remove most of this shift, because both set aside the provincial vote level. Raw seat counts and the efficiency gap do not.

Mechanism. Alberta's *Election Act*, RSA 2000, c E-1, s.112(1)(a.1) requires the election officer complete "a separate Statement of Vote for each voting area." Sections 113 and 124 apply this requirement — with "all necessary modifications" — to the advance vote count and mobile vote count respectively, meaning the per-VA reporting obligation extends by statute to every ballot type. The operative exception is s.112(2): "Despite subsection (1)(a.1), the election officer responsible for the count may combine the Statements of Vote for more than one voting area in the same electoral division if, in the opinion of the election officer, it is necessary to maintain the secrecy of voting." EA's practice of reporting advance and mobile totals at the ED level rather than the VA level may reflect an invocation of the s.112(2) secrecy exception; no public Elections Alberta source says so, and this audit draws nothing here from the author's election-officer work. Whether EA applies the s.112(2) exception as a blanket policy across all advance VAs or as an individual election-officer determination for specific low-population VAs is unknown; the question is included in the pending informal inquiry to EA (see VA 043 case study below). No change to the voting process, ballot design, or voter interaction would be required to publish VA-level advance totals above a minimum-count threshold. Under s.112(2)'s own framing, VAs where secrecy can be maintained without combination could be published separately, requiring only an administrative determination from the election officer.

VA 043 (ED 70, Lesser Slave Lake) as case study. One VA in the canonical file (ED 70, VA 043) received zero election-day votes in EA's published polling data. It is retained in the

shapefile with zero vote totals. VA 043 covers 4,832 km² in the northern portion of ED 70, contains 844 persons per the 2021 Census (from `data/va_pop_from_das.csv`), and recorded zero election-day votes — all votes from VA 043 residents entered EA's advance/mobile divisional total with no VA attribution. The specific mechanism is pending EA confirmation: s.120 mobile polling requires a facility type (treatment centre, supportive living facility, shelter, community support centre) VA 043's community does not appear to satisfy. The alternative is Special Ballot voting under s.52.2 remote-area designation, where no polling team visits and residents vote by ballot request. Either way the geographic signal is absent from published data. VA 043 is surrounded by NDP-majority VAs (VAs 041, 042, and 044 returned 52.4%, 53.6%, and 81.8% NDP respectively on election day), placing it in a northern cluster running 534 NDP / 535 UCP across VAs 029–051 — near parity, in contrast to the southern cluster's 29.6% NDP. The geographic partisan signal for VA 043's residents is entirely absent from any published data product. The 2025–2026 Electoral Boundaries Commission received submissions specifically describing the Indigenous communities in this northern area and ultimately invoked §15(2) to protect the riding. The commission's geomatics work was supported by EA GIS staff (EBC Final Report acknowledgements). Whether the commission requested or received VA-level advance vote data from EA — which would have provided a geographic picture of VA 043's voting — is unknown. A direct informal inquiry to EA is pending. A formal FOIP request is queued as the fallback. Full case study in `findings/lesser_slave_lake_va043_representation_gap.md`.

6. **Within election-day votes, multi-VA polling stations are split equally.** Where one polling station served multiple Voting Areas, Elections Alberta reports a single combined Statement of Vote, so `build_canonical_va_votes.py` divides that station's votes equally across the VAs it served — the only defensible split absent finer data. This affects 986 of 1,216 election-day stations (81.1%), which together cast 889,189 of 932,164 election-day votes (95.4%); the largest single station spans 22 VAs. For those votes the effective spatial unit is the station's VA group, not the individual VA, so the substrate's working resolution is coarser than the 4,765-VA count implies. The homogenization is common-mode across both proposals — it applies identically regardless of which 2026 map a VA lands in — and, by averaging within station groups, tends to *understate* fine-grained packing/cracking rather than manufacture it.

3.3 Cycle-lag robustness

The population data the commission uses carries a cycle-lag: the 2021 decennial census updated to a July 1, 2024 Office of Statistics and Information estimate. This choice reflects standard Alberta commission practice (the 2017 Bielby commission used the same basis) and aligns Alberta's statutory approach with other Canadian provinces, which employ diverse population inputs: Quebec uses electors-by-register, British Columbia uses Statistics Canada quarterly estimates, and Manitoba uses decennial census only. Under Alberta's Electoral Boundaries Commission Act, s.12(3) requires the Commission to use the population information in the decennial census, and s.12(5) lets it use "more recent information respecting the population of all or any part of Alberta in conjunction with" that

census. The TBF July 2024 estimate is used under s.12(5). This statutory flexibility positions Alberta within the practical middle of Canadian commission approaches: more administratively responsive than Manitoba's decennial-census restriction, yet more constrained than Quebec's live-register mandate. Alberta's cumulative population growth on a like-for-like *adjusted-estimate* basis is approximately **10% from July 1, 2021 (adjusted estimate 4,442,879) to Q2-2024 postcensal estimate (4,888,723)** and approximately **13% from July 1, 2021 to Q2-2025 (≈ 5.02M)**. The July 1, 2021 *adjusted* estimate of 4,442,879 is rebased on the 2021 census count with the net-undercoverage adjustment Alberta requires as the highest-undercount province. Earlier drafts cited 17.8% (2021→mid-2025) and 14.69% (2021→mid-2024); both numbers mixed the 2021 *raw census count* (4,262,635) with the *postcensal estimate* universe (4,888,723 at Q2-2024), a ~4.2 pp level shift attributable to net-undercoverage rebasing, not real growth. (T1.7 R1 Ref #13 caught the universe-mixing error; T1.7 R2 Ref #13 caught that round-1's "~10%" figure was labeled mid-2025 but actually corresponds to mid-2024 — mid-2025 like-for-like is ~13%; corrected 2026-06-12.) Corrected 2026-06-12 per T1.7 Referee #13 (Statistics Canada 91-528-X *Population and Demographic Estimates: Methods*; 2021 Census Coverage Study). The directional findings in this section are unchanged because they compare population *shares* within each vintage; the *level* corrections are flagged here so any cross-vintage growth claim made downstream uses the like-for-like adjusted basis. The audit's `findings/cycle_lag_analysis.md` computes how many electoral divisions flip ±25% window status when mid-2025 populations are substituted: 5 of 87 on the 2019 map, 0 of 89 on the majority 2026 proposal, and 5 of 89 on the minority 2026 proposal. ⚠ **Note:** A standalone cross-check verifying that every §5.1 verdict is identical whether computed against the 2021 census directly, the 2024 OSI estimate, or the 2025 TBF estimate (i.e., that directional findings are robust to intra-cycle population vintage) was intended but not produced as a standalone file (`analysis/reports/plan_b_cross_check.md` does not exist). Appendix C supplies a 2021-Census A1 computation for the 2019 map and both 2026 maps as the §12(3)-operative reference point.

Dataset-construction consequences of cycle lag (three-vintage sandwich). Beyond the verdict-robustness property above, the 4–14-year lag between commission data-basis and boundary retirement materially shapes *how* the audit's upstream pipelines construct their datasets. Any reconstruction of the commission's arithmetic has to reconcile three input vintages simultaneously:

- **2021 geometry + 2021 population.** Statistics Canada Dissemination Area (DA) polygons carrying 2021 census populations — the atomic unit used for Phase 4B DA-overlay.
- **2024 operative estimate.** The commission's July 2024 Treasury Board and Finance (TBF) estimate for each 2026 proposed ED — the operative published value against which the commission's variance tables were computed.
- **2023 voting substrate.** The 2023 Voting Area (VA) polygons carrying 2023 votes — the spatial substrate used for Phase 4C partisan-bias attribution.

The ratio between the 2021-population-sum-inside-a-2026-DPG-polygon and the commission's 2024 estimate of the same territory is **not** a clean scalar. Alberta's ~10% like-for-like growth between July 2021 (adjusted estimate 4,442,879) and Q2-2024 (postcensal estimate 4,888,723) was distributed unevenly (earlier drafts cited "14.69%" here — that figure mixed the 2021 raw census count with the 2024 postcensal estimate, a ~4.2 pp universe-rebase that is not real growth; corrected 2026-06-12 per T1.7 R2 Ref #13) — Calgary-ring cities grew faster than the province (OSI municipal estimates, July 2021 to July 2024: Chestermere about 26 %, Airdrie about 15 %), rural territories grew 0–5 % — so applying a flat provincial growth factor to a regionally heterogeneous population surface introduces a structural bias into Phase 4F's per-ED validation deltas. The 81 of 86 majority and 87 of 89 minority hardstop failures originally documented in `data/meta/INTEGRITY_STATUS.md` (computed against v0_5 DPG geometry; now bannered SUPERSEDED in `findings/phase4f_summary.json`) were a composite signal: real DPG transcription error plus cycle-lag growth heterogeneity, not separable from public data alone. **Canonical share-based recompute (T4.9-share closed 2026-06-12; `findings/phase4f_hardstop_canonical.md`).** The 2 % hardstop applied to raw 2021 census-count vs 2026 postcensal-estimate deltas conflates net-undercoverage rebasing (~4 pp province-wide) with actual per-ED drift, and was reported in an interim form on 2026-06-11 as "89 / 89 fail" (universe-mismatch). The substrate-honest version is a per-ED *share-of-provincial-total* comparison. Under the share-based test, **78 of 89 majority EDs and 72 of 89 minority EDs fail the 2 % share-drift hardstop** (median per-ED share drift 5.78 % majority / 5.79 % minority; max 39.24 % / 33.39 %, concentrated in fast-growth Calgary/Edmonton suburbs — Calgary-NE, Edmonton-Windermere, Calgary-Shaw, Calgary-South East, Edmonton-South). The universe-mismatch test raised the v0_5 counts (81/86, 87/89) to 89/89; the share-based test brings them down to 78/89 and 72/89. The audit's headline reading uses the share-based counts. Full treatment at `findings/cycle_lag_analysis.md` (§1); canonical re-run with share-based + universe-mismatch comparisons at `findings/phase4f_hardstop_canonical.md`.

Forward-modelling consequences for commissions. The 2021 decennial census — the Commission's statutorily-mandated baseline under §12(3) — is 6 years stale at the first election under the new boundaries (2027) and up to 14 years stale at the boundaries' retirement (potentially 2035).

For fast-growth metropolitan-fringe cities (Airdrie, Chestermere, Cochrane, Okotoks, Beaumont, Leduc, Spruce Grove, Fort Saskatchewan, Sherwood Park), this gap already moves per-ED population quotas by 10–15 % at the 4-year mark and by 40 %+ at the 14-year mark under current growth rates, independent of any drawing choice the commission makes.

For slow-declining rural districts (Peace River, Central Peace-Notley, Lesser Slave Lake), the gap erodes §15(2) special-rural-protection ratios asymmetrically: Lesser Slave Lake's mid-2025 §15(2) qualifying ratio drops past −50 % of the provincial mean under the cycle-lag

substitution, which could disqualify a district from its current legal basis before the cycle concludes.

Indigenous on-reserve populations face a third variant of the same problem: commissions inheriting the census's chronic 3–10 % on-reserve undercount see those communities structurally under-represented for the full 6–14-year cycle.

The gap is primary-source verifiable for the Kee Tas Kee Now Tribal Council member nations in northwestern Alberta — a regional tribal council whose member nations include communities among the 14 First Nations and Métis communities the EBC Final Report identifies within or adjacent to ED 70. ISC First Nations Population Profiles (April 2026, after the commission's data date; §12(3)(b) brings federal reserve population figures into the mandate only for reserves the census did not count) show registered population growth rates in excess of the provincial norm. (Note: the 14.69% figure cited in earlier drafts of this sentence was replaced 2026-06-12 per T1.7 R2 Ref #13 — it mixed the 2021 raw census count with the postcensal estimate universe; the like-for-like adjusted-estimate provincial growth for the 2021→2024 window is ~10%, documented in the §5.1.1 correction note above. Peerless Trout's ~7-year figure and the ~3-year provincial figure are not directly time-comparable; both are cited here for directional orientation.) Peerless Trout First Nation (Band 478) recorded a registered population of 1,155 in April 2026, up from 966 in the prior ISC profile — a 19.5% increase over approximately seven years, more than one-third above the provincial rate for the same period. Whitefish Lake First Nation #459 (Atikameg) shows a 2021 Census community population of 880 (Statistics Canada, Indigenous Population Profile 2021). 1,423 registered band members are listed on own reserve in the April 2026 ISC profile (total registered: 3,266, including off-reserve members living elsewhere in Alberta). Note ISC registered population on own reserve and census household population are distinct measures — the former counts registered band members who list the reserve as their address of record, the latter counts people physically present. Lubicon Lake Band No. 453, which operates on Crown land rather than a formal reserve, recorded a 2021 Census median age of 21.2 years. Whitefish Lake's census median age is 22.6 years. Median ages in the low-to-mid-twenties indicate cohorts entering peak fertility and early working-age years simultaneously — a demographic structure associated with above-average natural increase over the coming decade. A commission drawing the 2026 map on 2021/2024 TBF data works with a population basis for these communities stale not only in absolute terms but in growth-rate terms.

None of this is resolvable by audit methodology alone. The §12 statutory framework itself determines what baselines the Commission is permitted to consult. A legislative-reform proposal formalising a composite basis (TBF primary + StatsCan tie-breaker at ±2 % + AHCIP + CRA T1 cross-check + CEO as certifying authority) is outlined at `docs/act_amendment_proposal.md`. The audit offers this as a policy contribution, not a finding. Full treatment at `findings/cycle_lag_analysis.md` (§2).

Policy contribution: synchronise redistribution timing with census data release. The structural source of the 4–14-year cycle lag is timing: the Act ties a commission's appointment to

general elections (s.5(2): the first session after every second general election), not to the census. Canada's 2026 census, which is not a decennial census under the Act, was enumerated in May 2026. For 2021, Statistics Canada released population counts down to dissemination areas in February 2022, about nine months after enumeration. The current commission was appointed on March 28, 2025, three years after that release, and drew on 2021 census data updated to a July 2024 estimate. The Act could be amended to require the commission's appointment follow the release of census counts from the most recent enumeration. This would reduce the population-data age at the time of drawing from 4+ years to approximately 1–2 years, and would ensure fast-growth metropolitan-fringe communities whose populations change 20–30% per four-year cycle are accurately represented in the map the commission draws rather than in a retrospective correction the next commission inherits. The audit offers this as a policy contribution, not a finding.

Policy contribution: Elections Alberta should publish home-VA vote totals for advance ballots. In the 2023 provincial election, 809,660 NDP and UCP votes cast advance, mobile, or special (395,472 of them NDP) carry no Voting Area identifier in EA's published data (§3.2 item 5). The statutory framework is clearer than it initially appears: s.112(1)(a.1) of the *Election Act* requires a separate Statement of Vote per voting area, applied to advance counts through s.113 and mobile counts through s.124. EA's aggregate reporting practice may rest on the s.112(2) secrecy exception, which permits combining VAs when "necessary to maintain the secrecy of voting." The reform is not to create a new legal obligation but to provide guidance, or amend s.112(2), to require the secrecy exception be applied VA-by-VA against a minimum-count threshold — so only VAs where combination is genuinely necessary for secrecy are combined, while larger VAs are published separately. Publishing VA-level advance vote totals alongside the existing election-day VA breakdowns requires no change to the voting process, no additional interaction with the voter, and no new data collection — only a change to how EA applies a discretion the statute already authorizes.

The gap disadvantages not only external analysts but the Electoral Boundaries Commission itself. Commissioners are required by the EBCA to weigh community of interest — to assess whether geographic communities have coherent political identities worth preserving whole, or whether proposed boundaries divide natural constituencies. This assessment depends on understanding where voters actually live and how they participate. When advance voting accounts for approximately half of all votes cast and those votes carry no geographic attribution below the ED level, commissioners are recommending boundaries while working with the same incomplete spatial picture as external auditors. The voters list they consult shows where electors are registered. The vote results EA publishes show only where half of them voted. These are not the same thing, and the discrepancy is largest precisely in the high-growth suburban communities — Airdrie, Cochrane, Chestermere, Leduc — most contested in redistribution proceedings.

Publishing VA-level advance vote totals would allow complete-coverage VA-level vote attribution in future audits, provide commissioners with a full geographic picture of the communities they draw boundaries around, and bring Alberta's results reporting to the

granularity the EBCA's community-of-interest mandate implicitly requires. Standard minimum-count thresholds — already applied to election-day polling station results — would apply equally to advance VA totals, preserving individual ballot secrecy in low-turnout voting areas without limiting geographic transparency for larger communities. The audit offers this as a policy contribution, not a finding.

Cross-election asymmetry reversal in the retired blend model: mechanical explanation. A parallel sensitivity operates on the partisan side. The minority map absorbed three hybrid configurations the majority does not contain: Springbank-area townships (outer west Calgary suburbs), Bearspaw, and Cochrane. These communities are high-income, low-density outer suburbs whose two-party NDP/UCP vote share sits in the blend model's transition zone — high enough urban-weight sensitivity small shifts in the rural baseline produce large swings in the hybrid's attributed vote share. In 2023, outer Calgary suburbs returned NDP shares near the urban-core mean (2023 was a competitive cycle; suburban NDP performance was stronger than historical). In 2019, the same territories returned NDP shares closer to the rural baseline (in 2019, a UCP landslide, NDP support held up in the urban core but had shallower reach into outer Calgary suburbs). The audit's blend model applies a fixed geographic weight to both election years. What changes is the rural baseline being mixed in. Under 2023 votes, Springbank/Bearspaw/Cochrane territory makes the minority's hybrid EDs mildly more NDP-competitive than under 2019, which is why the minority asymmetry is negative under 2023 but positive under 2019. The blend code computes EG as (NDP wasted − UCP wasted) / total, so positive means UCP advantage, as in the glossary (the same code gives the 2019 map −2.64 %, read throughout as mildly NDP-favoured): under 2023 votes the blend read the minority as the more NDP-favourable map, and under 2019 as the more UCP-favourable one. The reversal is a property of the estimation model interacting with Alberta's election-specific suburban swing geography — not a measurement of a different underlying boundary configuration. §5.2.3 documents the blend's numbers: 2015 asymmetry +0.03 pp, 2019 +0.75 pp, 2023 −0.51 pp. The individual map EG signs DO flip under 2019 votes (both maps turn NDP-favourable at −1.32 % / −0.49 % per canonical Option C — see §5.2.8; the v0_8-based claim that "neither map's EG sign flips" was an attribution artefact, corrected in draft 2026-06-13 per T1.7 R2 S4). On the official files the inter-map asymmetry does not change direction: the minority stays the more UCP-favourable map in all three elections (Option C: +2.96, +0.83 and +3.92 pp), so the reversal described above belongs to the blend model alone.

---

4. Methods

This section describes the audit's methodology; results follow in §5. The methods are presented in the sequence they are applied: the symmetry and falsifiability discipline (§4.1), the vote-attribution pipeline used for all partisan-bias metrics (§4.2), the specific test

battery B1–B6 with thresholds and references (§4.3), and the legal-defensibility frame used to map findings to potential challenges (§4.4). Mathematical formalism for the four metrics is consolidated in Appendix D.

4.1 Methodology and integrity framework

4.1.1 Symmetry requirement

Every test applied to one map is applied identically to the others. Where a data gap prevents symmetric application, the gap is disclosed explicitly and the claim's scope is narrowed to what is symmetric.

4.1.2 Falsifiability gates

Each analytical stage produces a PASS/FAIL gate value before propagating downstream. Gates implemented:

- **G1 (carry-forward verification):** B1–B4 on 2019 baseline must reproduce the four-figure match to official totals (NDP 777,404 / UCP 928,900, two-party 1,706,304; arithmetic verified: 777,404 + 928,900 = 1,706,304; source: `data/raw/2023_results.xlsx`). Reproducible via `python3 analysis/scripts/packing_cracking_analysis.py`.
- **G2 (2026 estimate count):** Each map's ED estimate set must contain exactly 89 districts; total two-party election-day votes between 700,000 and 1.1M (the substrate holds about 0.9M; §3.2 item 5); NDP share within [0.40, 0.50]. `validate_2026_estimate()` in `packing_cracking_analysis.py`.
- **G3 (Calgary classification coverage):** A2 test requires zero residual unclassified Calgary EDs. Enforced programmatically in `a2_calgary_analysis()`.
- **G4 (A2 robustness):** A2 directional finding must survive alternative classification (2023 winner-based) or be flagged as classification-dependent. `a2_robustness_check()` implements the alternative.
- **G5 (Sensitivity range; retired with the blend model, C5):** B2 efficiency gap computed under urban weights 0.60, 0.70, 0.80, 0.85 (central), 0.90. Direction must be consistent across all five; magnitude range is reported alongside the central estimate. The gate tested the retired blend model; the current check is attribution-method sensitivity (C11).

4.1.3 What does not enter the report

- Any number not reproducible by running a checked-in script against checked-in data
- Any classification rule without a robustness check under at least one alternative
- Any language characterizing one map's features with stronger modifiers than the other's when the underlying facts are comparable
- Any "the numbers confirm X" framing in section preambles

4.1.4 Derived Provisional Geometries (DPG) — summary and canonical resolution

Prior to 2026-05-06, official Elections Alberta shapefiles for the two 2026 proposals had not been published. All pre-canonical 2026 boundary geometries were **Derived Provisional Geometries (DPG)** — polygons reconstructed from commission-published PNGs via a ten-stage pipeline (raster trace → topology cleanup → population-swept hybrids → CSD/DA anchoring → confidence propagation → multi-source assembly → four-phase perfecter → nested-polygon ownership inversion). Two error modes govern DPG-dependent metrics:

- **Perimeter-mode uncertainty (±500 m typical):** boundary localisation error affecting compactness scores (Polsby-Popper, Reock) and fine-grained vote attribution near boundary lines.
- **Area-mode uncertainty (Tier-dependent):** whole-polygon-territory mismatch affecting DA-overlay populations and polygon-intersection tests. Tier A EDs (da-anchored, municipal-anchored) carry shapefile-grade fidelity. Tier C EDs (v7 visual transcription) are subject to documented area-mode errors and are excluded from primary findings.

Official shapefiles received 2026-05-06. Findings designated [C] (canonical) throughout this report were recomputed on official Elections Alberta shapefiles. DPG-era results remain in the record per pre-registration obligation and are superseded by their canonical equivalents where both exist. Findings not marked [C] may be DPG-derived and are subject to the sunset clause. See `analysis/methodology/canonical_shapefile_log.md` for the full reconciliation of which findings have been recomputed on official geometry.

Sunset clause — satisfied, with material changes disclosed. The pre-registered commitment to recompute all geometry-dependent metrics within two weeks of official shapefile release was triggered on 2026-05-06; Phase 4C was done on 2026-05-18, and the canonical ensemble was rerun clean on 2026-07-12 (C9, C10). Two findings did change materially on canonical recomputation and are flagged here rather than left to the deltas file:

1. **Municipal anchoring (§5.8.5) does not separate the maps on canonical geometry.** The DPG-era reading of 14.5 % / 71.0 % / 4.9× ratio collapsed to 71.8 % / 80.0 % — both close to the 2019 map's 75.1 % — on canonical geometry. The anchoring finding has been retired; `archive/dpg_era/municipal_anchoring_analysis.md` carries a superseded banner.
2. **The minority's declination value passed through a transient attribution-refinement sign change, and a code-side sign convention error was corrected 2026-06-12 (Amendment 5, Part 9).** Per `findings/post_audit_recompute_deltas.md` (sign-convention notes updated for the sign correction, Amendment 5, Part 9): the v0_8 DPG-substrate reading of δ = −0.0666 moved to **+0.0105** on the canonical first-pass substrate, then settled at **−0.0770** on the final canonical run after the Vote-Anywhere attribution correction (~9.4 % of votes) landed. Those values were under the implementation's *swapped-operand* convention. Under the Warrington 2018 convention (positive δ = UCP-favoured), the equivalent canonical final value is **+0.0770**, sitting at p98.79 — UCP-favoured tail. The first-pass canonical reading (+0.0105 under the old convention; −0.0105 under

Warrington) is superseded by the final canonical. Both the v0_8 and the final canonical agree on the same direction once corrected: minority is UCP-favoured on declination (matches EG, MM, s50). Any reading still citing "p62.2 / near median" or "p1.21 NDP-tail" derives from a superseded substrate or the pre-correction code sign and is corrected here. Appendix D.3 documents the convention, how the error was found and the verification; Amendment 5, Part 9 records the correction.

Several other findings also changed on canonical geometry: Calgary-Foothills-Airdrie West's city-limit anchoring went from 0 % to 10.8 % and the Airdrie highway refutation no longer reproduces (C48); the Airdrie cracking signature and the Cochrane pattern were rescored as not detected (C48); the packing signature fails its margin test (C50); the minority's seats@50/50 now sits below the ensemble's maximum, not above it (C22); and the Reock and Polsby-Popper between-map asymmetries reversed (C2, C3). Full reconciliation is at `analysis/methodology/canonical_shapefile_log.md` and `findings/post_audit_recompute_deltas.md`.

The full ten-stage DPG pipeline — construction methodology, error progression table, nested-polygon ownership-inversion algorithm (extends Sester 2000; Saalfeld 1988), and programmatic city-centre alignment proof — is documented in the companion methods paper: `findings/methods_paper_draft.md`.

4.1.5 DPG construction pipeline — multi-source assembly (v0_7)

Full ten-stage pipeline (raster trace → topology cleanup → population-swept hybrids → CSD/DA anchoring → confidence propagation → multi-source assembly → four-phase perfecter → nested-polygon ownership inversion) documented in the companion methods paper (`findings/methods_paper_draft.md`). Summary of methodological findings running counter to expectation: §5.0.2.

4.1.6 v0_8 coverage diagnostics — inheritance fill and geometric refinements

Full methodology in companion methods paper (`findings/methods_paper_draft.md`). Key coverage findings: 21 of 89 majority EDs have zero geometry in v0_7 and inherit empty into v0_8; Phase 3 spatial-index gap-fill systematically inflates rural ED areas in v0_8 vs v0_7; Calgary-Falconridge-Conrich is fully nested inside Airdrie-East in v0_7/v0_8 (v0_8.1 nested-polygon ownership-inversion refinement applied); v0_8.2 inheritance fill assigns 21 majority + 12 minority EDs from 2019-Tier-A predecessors. Findings in §5.0.2 items 6–9; caveats propagating to downstream findings in §4.1.8.

4.1.7 City-centre alignment proof

Point-in-polygon plausibility check against Statistics Canada city-centre representative points: 9 of 10 Alberta city centres land in correctly-named EDs in the v0_8.1 refined majority geometry; the single miss (St. Albert) falls in the gap-fill-inflated West Yellowhead

polygon. The v0_8 minority geometry places only 4 of 10 correctly: six city centres fall in its over-extended Peace River polygon (`data/outputs/topology_alignment_proof.json`). Full findings in §5.0.2 item 9.

4.1.8 v0_8 geometry caveats propagating to downstream findings

Two imperfections propagate to Run #4 (§5.4.4) and related downstream findings: (1) inherited urban polygons trace 2019 boundaries rather than 2026 commission boundaries for 21 majority and 12 minority EDs; (2) the v0_8 minority's Peace River polygon is over-extended by Phase 3 gap-fill, absorbing 6 of 10 city-centre landmark points (§4.1.7). Both imperfections are disclosed where downstream findings cite v0_8 numbers.

4.2 Vote-attribution pipeline

Current pipeline (Phase 4C, since 2026-05-18). 2026 ED-level votes are built by exact spatial attribution: each of the 4,765 Voting Areas carries its 2023 election-day NDP and UCP votes, and each VA is assigned to the 2026 ED that contains its centroid on the official Elections Alberta shapefiles (`analysis/scripts/phase4c_canonical_attribution.py`). No estimation or blending is applied. Election-day votes only are used (§3.2 item 5), and multi-VA polling stations are split equally (§3.2 item 6). The check on this pipeline is attribution-method sensitivity (C11).

Retired pipeline (v0.2 blend, superseded 2026-05-18; C5). Earlier estimates mapped each 2026 ED to its 2019 predecessor(s) using an explicit dictionary (`MAJORITY_2026_MAPPING`, `MINORITY_2026_MAPPING`). Three mapping types:

- `direct`: 2026 ED covers approximately the same territory as a 2019 ED; use 2019 votes directly.
- `blend`: 2026 ED combines a 2019 urban core with rural absorption; blend 2019 core vote with the 2023 observed Rest-of-Alberta NDP share (33.5%) using urban weight 0.85 (applied identically to both maps).
- `merge`: 2026 ED combines two 2019 EDs; weight each part explicitly.

4.3 Test battery

Channel structure and ordering rationale. The quantitative evidence runs in a fixed, dependency-ordered sequence:

- **Channel 1 — MCMC ensemble + inter-map permutation test.** Asks the broadest question first: is the minority map anomalous relative to a neutral redistricting distribution, and is the gap between the two commission maps larger than neutral plan pairs are apart from each other? This establishes there is a real inter-map distance to explain.
- **Channel 2 — SZAT.** Decomposes *which specific boundary decisions* produced the confirmed gap. Runs after Ch1 because decomposing a gap not yet established as real would be decomposing noise.

- **Combined-channel headline: Ch1 doubled for two channels (Bonferroni)** (corrected 2026-06-10; restated 2026-06-12 per T1.7 R2 Ref #1). The earlier framing — "Ch1 and Ch2 combined via Fisher's method only after confirming the two tests are uncorrelated (`analysis/methodology/fisher_independence_defense.md`, ρ = −0.0014)" — was dropped at §5.4.9 because the ρ = −0.0014 check measures correlation across two *unpaired* Monte Carlo streams rather than the dependence between the test statistics under the null map distribution. Under positive dependence Fisher is anti-conservative (Brown 1975), so the audit's operative joint figure is **Bonferroni: $p \approx 1.76 \times 10^{-6}$**, the parametric Ch1 value doubled for two channels. The doubling is valid under arbitrary dependence; its input is a model extrapolation past the sampled maximum, and the sample alone supports p below about 6.9×10^{-4}. The Fisher value (4.61×10^{-8}) is reported in §5.4.9 as the dependence-naive figure for methodology completeness only.
- **Channel 3 — Neighbour-Drain.** A pre-registered structural observation reported per pre-registration obligation. Does not feed into the joint headline. Result does not alter the Ch1-based verdict.
- **Two-Lane Scorecard.** Synthesises all channels. Scored last because it cannot be completed until all tests are run.

Sign-convention glossary. Throughout this paper, for every partisan-bias metric: **positive value = UCP advantage** (UCP wastes fewer votes per seat / carries the higher-than-median district / wins more seats at 50/50 / has shallower winning-district-margin angle than NDP), and **negative value = NDP advantage**. (Corrected 2026-07-13 — DOCUMENTED CORRECTIONS C13: this glossary sentence had the polarity backwards, contradicting its own worked example two paragraphs below and every other EG/MM/declination direction statement in this report.) The sign convention is chosen for readability against seat-count outcomes, not to match the Stephanopoulos-McGhee 2:1 slope convention (which labels positive EG as "first-party disadvantaged"). Readers cross-referencing the S-M literature should invert the sign-label, not the finding. Both conventions agree on the *ordinal* ranking of the three maps. Full glossary and cross-convention reconciliation in `analysis/methodology/sign_convention_resolution.md`.

- **B1:** Vote distribution histogram across 10 margin bins from UCP +25%+ to NDP +25%+. (Descriptive; no formal literature reference.)
- **B2:** Efficiency gap (Stephanopoulos and McGhee 2015): $\text{EG} = (W_{\text{NDP}} - W_{\text{UCP}}) / N$ where wasted votes include loser votes plus winner votes above the threshold. **Sign convention.** Under this formula, positive EG means NDP wastes more votes than UCP — i.e. UCP is advantaged in seat-outcome terms. Negative EG = NDP advantaged. The Stephanopoulos-McGhee 2015 reference text uses the same wasted-vote formula but anchors the sign discussion around a "first party / second party" labelling some readers find ambiguous; the convention used here ("positive EG = UCP advantage") fixes the labels to the parties measured. All reported EG values in this audit follow this convention: the minority's +3.96% is UCP-favoured, the majority's +0.04% is essentially neutral, and the 2019 enacted map's +2.41% on the canonical

election-day substrate is slightly UCP-favoured in absolute terms and inside the neutral range (p69.46). The 2019 map's −2.64% is on a different substrate, the full statement of vote, where it reads as mildly NDP-favoured; the two figures should not be compared directly. A reader comparing against S-M literature should map "positive EG = UCP advantage" here to the corresponding direction in S-M's first-party / second-party framing, not invert the finding.

- **B3:** Mean-median gap (McDonald and Best 2015): $\text{MM} = \bar{v} - \tilde{v}$ for NDP vote share.
- **B4:** Seats-votes under uniform swing to 50/50 provincial share (Gelman and King 1994; Grofman 1983).
- **B6:** Declination (Warrington 2018). For each party, take the angle from the 50 % point to its mean vote share in the districts it won, scaled by its seat share; declination is 2/π times the NDP angle minus the UCP angle (Appendix D.3). Positive = UCP advantage. The direction disagreement once reported in §5.2.4 was a sign error (Amendment 5, Part 9).

The seat-vote-curve symmetry principle underlying B4 traces to Grofman (1983) and King and Browning (1987), later formalized as a Bayesian estimator by Gelman and King (1994). The efficiency gap and mean-median are two of the most widely-cited partisan-bias metrics in the post-*Gill v. Whitford* literature; Stephanopoulos and McGhee (2018) revisit the efficiency-gap debate and acknowledge the metric's sensitivity to modeling choices, which this audit's attribution-method sensitivity check in §5.2.2 and §5.2.7 quantifies for the Alberta context. Katz, King, and Rosenblatt (2020) argue that any valid measure of partisan bias must satisfy symmetry and critique single asymmetric metrics as inadequate. The audit's ensemble measures departure from neutral plans, not from symmetry, and it does not claim to meet their criterion; in absolute terms the minority is closer to an even split at 50/50 than the majority (46 UCP seats of 89 against 41).

Mathematical definitions for EG, MM, declination, and the Polsby-Popper and Reock compactness metrics are in Appendix D.

4.3.1 Multiple-comparisons handling: Exploratory screening (current run) versus confirmatory testing (November 2026)

Exploratory vs. confirmatory framing. The current detection run applies six correlated tests across multiple analytical dimensions (not all independent — see the BH-table dependence-disclosure paragraph below). This creates a multiple-comparisons burden if the results are interpreted as confirmatory hypothesis tests, where each test is adjudicated at $\alpha = 0.05$ independently and then combined. The audit's response is to frame this run as **multi-dimensional screening analysis** (corrected terminology 2026-06-12 per T1.7 Referee #16; earlier drafts called this "Bayesian-screening" — that label was unsupported by the actual machinery, which uses no prior, no likelihood, and no posterior; full Bayesian updating is explicitly ruled out at the §4.6 framework-defense paragraph). What the audit actually does is a frequentist screen reported descriptively (per-dimension percentile placements) plus a

synthesis claim about directional agreement; the screening / confirmatory distinction is honest and serves the same role as the "Bayesian-screening" label was intended to, without claiming machinery the audit doesn't deploy.

Under the multi-dimensional screening frame, the six-dimensional battery (population variance, partisan-bias metrics B2–B6 — declination sign-corrected (Amendment 5, Part 9), compactness, geographic coherence, procedural findings) serves as a screen to identify potential signals. The primary inferential claim is directional consistency *across* dimensions, not significance *within* any single dimension: "six correlated lines of evidence point in the same direction" is the audit's finding, not "six individual tests reject the null at classical confidence." This framing aligns with the pre-registration posture stated in §5.3.1: the current findings are exploratory. The prospective test is the November run on the advisory panel's map, under `preregistration/november_2026_scoring_spec.md` (June 2026).

Confirmatory protocol (November 2026). The November confirmatory run will apply a pre-registered formal hypothesis-testing framework with explicit multiple-comparisons correction. The Benjamini-Hochberg false-discovery-rate control (described below) is the proposed correction structure for the confirmatory pass. The current run's BH table (provided for reader reference) shows what the p-value landscape would be if classical hypothesis-testing were applied retroactively; but the exploratory-to-confirmatory distinction means the current run does not carry the inferential weight a BH-corrected significance claim would carry.

Exploratory findings as evidence, not conclusions. The six-dimensional directional consistency reported in §5.2–§5.8 and summarised in §6 is evidence-suggesting (pointing toward systematic asymmetry in boundary drawing and outcome) rather than evidence-concluding (determining a court would find the asymmetry unjustified under the Saskatchewan Reference effective-representation standard). The November confirmatory pass will sharpen this by applying formal hypothesis-testing machinery. The current exploratory findings provide the pre-hoc signal motivated those pre-registered tests.

Benjamini-Hochberg correction for the confirmatory pass. The audit does not rely on any single statistical test for its conclusions. The primary inferential frame is directional consistency across multiple correlated dimensions (§6, §4.6). For the November confirmatory test, a formal Benjamini-Hochberg (BH) false-discovery-rate correction will be applied so the multi-test battery can be evaluated at α=0.05 family-wise. The reference table below shows the p-value landscape under BH correction. It is provided here to show readers what the correction structure will be when applied confirmatorily.

Scope. The table includes all formal tests yielding a computable p-value against an explicit null distribution. Purely qualitative structural checks (packing/cracking/engineered-boundary signatures, municipal anchoring ratio) are not included because they do not produce p-values. The Fisher combined result ($p = 4.61 \times 10^{-8}$) is retired (see §4.3.3) and is excluded from the battery; the operative joint figure (the parametric Ch1 value doubled for

two channels, 1.76×10^{-6}, a model estimate) is likewise excluded because it is a function of Ch1, which already appears as Rank 2.

p-value derivation for MCMC percentile tests. A minority map at ensemble percentile p_pct in the UCP-favoured tail yields a one-tailed p-value of (1 − p_pct/100). A majority or minority map in the NDP-favoured tail yields p = p_pct/100. Row 3 (Seats@50/50): the raw 250k ensemble found 0/250,000 neutral plans exceeding the minority value ($p < 4\times10^{-6}$). The 250k full-coverage rescore placed it at p94.3 (inside the neutral band; the flag was dropped). The 1,010,000-plan canonical run (§5.4.9, seats@50/50 n_eff=1,413) reinstates the seats@50/50 flag: 1,010,000-plan percentile = 99.99. Row 3 counts as a positive finding under the 1,010,000-plan run.

RANK	TEST	MAP	P (RAW)	P (BH-ADJ)	A = 0.05
1	Moran's I spatial clustering on NDP share (z = 12.15)	2019 substrate	4.8×10^{-34}	5.3×10^{-33}	**PASS**
2	Mahalanobis joint tail — Ch1 (canonical ensemble; parametric, C10)	Minority	8.8×10^{-7}	4.8×10^{-6}	**PASS**
3	Seats@50/50 vs canonical ensemble (69 of 1,010,000 plans exceed it, all at 45/87; p99.99)	Minority	6.8×10^{-5}	2.5×10^{-4}	**PASS**
4	Lopsided Margins t-test — Wang (2016), t = 3.80 (canonical 2026-06-11)	Majority	2.7×10^{-4}	7.4×10^{-4}	**PASS**
5	Mean-median vs canonical ensemble (p99.97)	Minority	3.3×10^{-4}	7.4×10^{-4}	**PASS**
6	Lopsided Margins t-test — Wang (2016), t = 3.17 (canonical 2026-06-11)	Minority	2.2×10^{-3}	3.8×10^{-3}	**PASS**
7	SZAT bootstrap — Ch2 (10,000 permutations; i.i.d.-flip null, retired: block-permutation p ≈ 0.19)	Minority	2.4×10^{-3}	3.8×10^{-3}	**PASS** (retired)
8	Population MedAD vs canonical ensemble (p99.1; ±12.5% proposal band only, p0.013 under the ±25% statute band)	Minority	8.7×10^{-3}	1.2×10^{-2}	**PASS** (band-conditional)
9	Mean-median vs canonical ensemble (p0.99, NDP-tail; 1,010,000-plan canonical run, seed 1432864451 — corrected 2026-06-14 per T1.7 R2 S19 re-audit; prior note "corrected per S19 to p0.85" had the direction inverted: p0.99 is the CSV value, p0.85 was a pre-canonical-run intermediate)	Majority	9.9×10^{-3}	1.2×10^{-2}	**PASS**
10	Declination vs canonical ensemble (p98.79, UCP-tail — corrected sign per Amendment 5, Part 9)	Minority	1.2×10^{-2}	1.3×10^{-2}	**PASS**
11	Efficiency gap vs canonical ensemble (p94.54)	Minority	5.5×10^{-2}	5.5×10^{-2}	FAIL

m = 11 tests (NOT all independent — see dependence-disclosure note below). Sorted by raw p ascending. BH-adjusted p_(i) = min over j ≥ i of (p_(j) × m / j) (standard BH step-up; Benjamini–Hochberg 1995, JRSS-B 57(1)). Raw p for the ensemble rows is the canonical ensemble's tail fraction (`findings/joint_outlier_score.json` `marginal_tail_p`; `data/outputs/simulated_ensemble_percentiles_canonical.csv` for MedAD); for the Lopsided Margins rows it is `lopsided_p` in `findings/extended_partisan_metrics_canonical.json`. Re-sorted + recomputed 2026-06-12 per T1.7 Referee #1 / #6 / #16 findings: the prior table was mis-sorted (rank 9 preceded rank 10) and the published adjusted p-values violated the

monotone step-up rule. Row 2 now carries the clean rerun's 8.80×10^{-7} (C10; it carried the scrapped run's 1.4×10^{-6}). The table counts 10 PASS / 1 FAIL, but not every pass counts toward the minority's UCP-direction finding: row 1 is a 2019-substrate property, row 7 (SZAT) is retired under the block null, rows 4 and 6 point in the NDP direction (see the directional caveat below), row 9 is the majority's NDP-tail result and row 8 holds only under the proposal band. The rows that count are 2, 3, 5 and 10.

Dependence disclosure (added 2026-06-12 per T1.7 Referee #1, #6, #16). The Mahalanobis row (rank 2) is a deterministic function of the same four ensemble metrics that appear individually as rows 3, 5, 10, and 11; row 8 (population MedAD) is a separate structural-lane statistic, and it passes only under the canonical ±12.5% proposal band (§5.4.9). Rows 4 and 6 (Lopsided Margins majority/minority) share one vote substrate. The standard BH controls FDR only under independence or PRDS (Benjamini–Yekutieli 2001, Ann. Statist. 29(4)); the table is therefore a *reference landscape*, not an independent-test family.

BY adjustment under dependence (T1.8 closed 2026-06-12). Under the BY rule $q(i) = p(i) \times m \times H_m / i$, *where* $H_m = \Sigma_{k=1..m}(1/k) = 3.0199$ *for* $m = 11$, *the adjusted p-values rise by a factor of 3.02 across the board:* 1.6×10^{-32}, 1.5×10^{-5}, 7.6×10^{-4}, 2.2×10^{-3}, 2.2×10^{-3}, 1.1×10^{-2}, 1.1×10^{-2}, 3.6×10^{-2}, 3.7×10^{-2}, 4.0×10^{-2}, 1.6×10^{-1} *(rank 1→11). At* $\alpha = 0.05$ *family-wise: rows 1–10 still* PASS*; row 11 (Minority EG) still FAILS*.* The audit's headline (10 PASS / 1 FAIL) is preserved under the dependence-robust adjustment; row 10 (declination) is now the closest-to-margin pass (4.03×10^{-2} vs α=0.05) but does not flip. This closes T1.8.

Reference result for confirmatory testing (November 2026). The table shows what the BH-corrected landscape would yield: 10 / 11 tests would pass BH correction at α = 0.05 under the confirmatory protocol. The sole failure is Minority EG (raw p ≈ 0.055, BH-adjusted p ≈ 0.055), which the audit already retracts from its outlier-flag set in §5.4.9 on independent grounds (the 1,010,000-plan canonical run places minority EG at p94.54, below the p95 threshold). The four rows that count toward the minority's UCP-direction finding (2, 3, 5 and 10) all pass BH correction; row 10 is the closest under BY. This table is provided as reference material so readers can see the correction structure governing the November confirmatory pass. It is not a retroactive inferential claim on the exploratory current run.

Scope note. The Lopsided Margins finding (rows 4 and 6) is present in all three maps including the 2019 enacted baseline and is explicitly described in §5.2.9 as a structural property of Alberta's political geography, not a distinctive feature of either 2026 map. Its inclusion in the BH battery is conservative (reduces the effective discovery rate for any new finding) but does not change the conclusion.

Directional misuse caveat (added 2026-06-12 per T1.7 Referee #6). Wang (2016)'s lopsided-margins t-statistic flags the *seat-majority party* (UCP, the dominant party in Alberta's 2023 substrate) as the *packed* party, which is structurally an NDP-favourable observation (UCP wastes votes in landslide wins). Counting positive-t Lopsided rows as "PASS" *alongside* UCP-favoured findings (mean-median, declination, seats@50/50) mixes directions in the synthesis: rows 4 and 6 are technically NDP-favourable evidence on the same map the other rows flag as UCP-favourable. The 4-of-4 partisan-bias agreement reported elsewhere in the paper relies on the EG family + s50 + declination, *not* on Lopsided Margins. Rows 4

and 6 are reported here for transparency under the m=11 BH battery but should not be read as adding to the UCP-favoured-direction count.

EG threshold MC-error caveat (added 2026-06-12 per T1.7 Referee #6 D15). The Phase 4C canonical minority EG (+3.96 %) lies 0.14 pp below the Alberta-calibrated 4.10 % threshold; the like-for-like canonical-ensemble value gives 0.08 pp gap. At ESS ≈ 1,413–1,522, the order-statistic standard error on the p95 threshold and on the p94.54 percentile each exceeds 0.08 pp. The sub-threshold call (row 11 FAIL) is therefore *indeterminate* within Monte Carlo precision, not robustly FAIL. This does not promote the row to PASS — the audit retains the FAIL — but the indeterminacy means any verdict re-litigation should not rely on the 0.08–0.14 pp gap as evidence of clear sub-threshold status.

4.3.2 Bonferroni correction as a conservative alternative

While Benjamini-Hochberg correction controls the false-discovery rate and is the chosen method for the confirmatory protocol, a simpler alternative exists: the Bonferroni correction, which controls the family-wise error rate (FWER) — the probability of any false positive across the entire test battery. The Bonferroni method is more conservative: for m = 11 tests (NOT all independent — see the §4.3.1 dependence-disclosure paragraph; corrected from "independent" 2026-06-12 per T1.7 R2 Ref #1) at α = 0.05 family-wise, the per-test threshold becomes α / 11 ≈ 0.0045 (compare to BH's step-up procedure which is less restrictive).

Applied to the current audit's findings: the two largest p-values in the battery are Minority EG (canonical p = 0.055, BH adj 0.055, FAIL) and Minority Declination (canonical p = 0.012, BH adj 0.013, PASS post-correction; Amendment 5, Part 9). Under Bonferroni at m = 11, α/11 = 0.00455. Ch1 Mahalanobis ($p = 8.80\times10^{-7}$) clears α/11 by **three orders of magnitude**; SZAT (p = 0.0024) clears α/11 by **a factor of ~1.9** under standard i.i.d.-flip permutation (not "multiple orders of magnitude" — corrected 2026-06-12 per T1.7 Referee #1). However, under a block-permutation null that corrects for spatial autocorrelation across adjacent Voting Areas — the 2,110 swing-zone VAs cluster into a single connected component of 2,086 VAs, violating the independence assumption — SZAT returns p≈0.19, not significant. SZAT is therefore retired as a confirmatory channel (see §5.2.10); its standard-permutation result is exploratory context only. The audit's structural findings — which rest on the directional consistency of multiple correlated dimensions rather than on any single test — survive Bonferroni correction. Ch1 alone (parametric $p = 8.80\times10^{-7}$, a model extrapolation past the sampled maximum; the sample alone supports p below about 6.9×10^{-4}) is the headline; the parametric value doubled for the two channels examined — Ch1 and Ch2, which share the same underlying 2023 vote substrate and are not independent (Brown 1975) — yields 1.76×10^{-6} (= 2 × 8.80×10^{-7}), about 1 in 568,000, a model estimate extrapolated beyond every sampled plan, not a bound; allowing for the covariance being estimated from the chain (Hotelling T^2, 1.11×10^{-6}, `findings/joint_outlier_score.json`), the same doubling gives 2.22×10^{-6}, about 1 in 450,000. This is the updated figure following the 2026-07-12 ensemble rerun (C10); the earlier text quoted "p ≈ 6.87×10^{-8} (≈ 1 in 15 million)" from the (separately

retired) Fisher combination, computed at the time from the chain-1-duplicated ensemble; the current Fisher recomputation on the clean rerun gives $p \approx 4.61 \times 10^{-8}$, but Fisher remains retired regardless (channel-independence assumption, not an ensemble-quality issue) and is not the operative figure either way. The doubled figure is still extreme — well beyond any standard significance threshold — and the ×2 factor covers any dependence between the two channels examined; its Ch1 input is still a model extrapolation. The choice of BH over Bonferroni for the confirmatory protocol reflects the audit's frame (multiple exploratory dimensions, not a single pre-registered hypothesis test) and the principle BH better balances discovery power with false-discovery control in high-dimensional exploratory settings.

4.3.3 Pre-registration record

The table below is the canonical lookup for pre-registration status of every quantitative test in the audit. Full provenance detail is in `analysis/methodology/null_hypothesis_and_exoneration_criteria.md`; full amendment history is in `findings/pre_registration_amendment_log.md`.

TEST	PRE-REGISTRATION ANCHOR	TIMING RELATIVE TO DATA
Ch1 — Mahalanobis joint outlier (§5.4.9)	Seeds derived from public drand round 5,500,000 (emitted 2025-10-14), with salts fixed in code on 2026-04-27; see `analysis/scripts/drand_seed.py` and `docs/FROZEN_MANIFEST.md`	The salts' commit predates offici (2026-05-06); the evidence is tl 2026-05-12. Specific test name not named in OSF. **Exploratory.**
Ch2 — SZAT boundary-choice bootstrap (§5.2.10)	AsPredicted #289,469 (filed 2026-05-07; made public 2026-05-07); OSF:6pt83 (filed ~3 h after shapefile commit — cannot be treated as pre-dating the data)	Numerical results were known to **Exploratory-reproducible.**
Ch3 — Neighbour-drain adjacency (§5.3.5)	OSF:r3zm7 / AsPredicted #289,451 (OSF registered 2026-05-06 21:50 UTC, about six hours after the shapefiles arrived)	The registration reports the offic counts it predicts from; the cont were not yet computed. Predicti about 91% of the time under ran (both maps inside the null) failed
Phase 2 comparison (qsgy8 Part A)	OSF:qsgy8 / AsPredicted #289,452 (registered 2026-05-06, after the shapefiles arrived; minority-map metrics not yet computed)	H2 (the minority map would be l H3 (the minority's population M/ failed: EG +3.96 % against +0.04 **Registered predictions, failed.**
Bonferroni Ch1 + Ch2 (§5.4.9) — supersedes the earlier Fisher combination	Combination method not pre-registered. The earlier Fisher framing relied on a "ρ = −0.0014" (`analysis/scripts/validate_fisher_independence.py`; `analysis/methodology/fisher_independence_defense.md`) independence check that measures correlation across unpaired Monte Carlo streams, not the test-statistic dependence under the null map distribution; retired 2026-06-10 and confirmed retired 2026-06-12 per T1.7 R2 Ref #1. The parametric Ch1 value doubled for two channels ($p \approx 1.76 \times 10^{-6}$, updated 2026-07-12 per C10) is the audit's joint headline.	**Exploratory.**

TEST	PRE-REGISTRATION ANCHOR	TIMING RELATIVE TO DATA
B7 — Intermap permutation test (§5.2.11)	OSF:yvc7g (filed 2026-05-10; drand seed 1823538405 derived from beacon round 5500000, which does predate shapefile receipt)	Post-dates shapefile receipt (202 canonical ensemble run (see `analysis/methodology/interma` §AV6). Methodology and directio the test executed. **Pre-registere not prospective relative to dat** 08: this row previously read "Pre registered." — contradicting the disclosure and the design doc's c
Municipal anchoring (§5.8.5)	OSF:s58a6 (filed 2026-05-10)	Post-dates shapefile receipt (202 drand-pinned seeds and channel prospective test definitions (see Finding did not hold on canonica close to the 2019 map's 75.1%). this row previously read "Pre-dat registration table in `reports/academic/data_supple` 2026-05-10 filing date.)
November 2026 91-seat scorecard (§5.5 prospective)	`preregistration/november_2026_scoring_spec.md` (June 2026, dated in this repository) decides the verdict. OSF:qsgy8 Part B (registered 2026-05-06) registers four tripwires (MO #1–#4), reported beside the verdict; OSF 9wp5y (2026-05-07) holds the 17-test checklist, which was scored on the panel's map on 2026-11-09, after its 72-hour window (`findings/checklist_9wp5y_panel_map.md`). The November drand round is to be pinned at or after the map's release.	The map (the advisory panel's, d not exist when these were writte
Forest-ReCom sampler-robustness check (§5.2.7)	OSF:he53s (filed public 2026-07-09 at 23:42 MDT, before execution; executed 2026-07-10)	Registration pre-dates the check ReCom run); the underlying canc existed. **Pre-registered robustn** 2026-07-14 — previously cited omitted from this table).
Lane 3 — process scorecard (Lunty committee process, prospective; commission process, retrospective)	OSF:u47bq (filed 2026-07-14; embeds `preregistration/lane3_process_scorecard_draft.md` verbatim at commit `694bbf36` with its SHA-256)	The committee's final process re filing; criteria frozen. Applied to commission process the scoreca **retrospective/descriptive only** (registration). **Prospective pre-re November process evaluation.**

What is and is not pre-registered. *The audit's headline statistic — Ch1 Mahalanobis $p = 8.80\times10^{-7}$, doubled for two channels to 1.76×10^{-6} (both parametric model estimates; updated 2026-07-12 per C10) — is not a classical pre-registered result: neither the specific ensemble metric nor the combination method was named or specified on OSF before data was examined, though both channels' seeds derive from a public drand round: Ch1's salt was fixed in code before the official shapefiles arrived, and Ch2's (SZAT) about six hours after they arrived (Amendment 5, Part 30; dated by the git record). (An earlier Fisher combined figure, $p \approx 4.61\times10^{-8}$, assumed channel independence and is retired; the doubled Ch1 figure is the successor — see §4.3.3 and §5.4.9.) The findings are therefore best characterised as exploratory-reproducible — the pipeline reproduces the headline against checked-in data, and the base seed re-derives exactly from round 5,500,000's public randomness (the round itself was public from October 2025, so the seed's timing rests on when the salt was committed, which only the git record shows), but the specific test*

combination was not externally time-stamped before results were seen. The November 2026 pass (`preregistration/november_2026_scoring_spec.md`, written in June 2026 before the panel's map existed; qsgy8's tripwires reported beside it) will provide the prospective test.

Multiple-comparison strategy (revised 2026-06-10; SZAT retirement note added 2026-06-13; updated 2026-07-12 per C10). Channel 1 (Mahalanobis joint outlier, §5.4.9) is the headline. Channel 2 (SZAT bootstrap, §5.2.10) addresses a structurally different question — boundary-choice efficiency rather than ensemble position — but under a block-permutation null correcting for spatial autocorrelation across adjacent Voting Areas it returns p≈0.19 (not significant); SZAT is therefore retired as a confirmatory channel and treated as exploratory context only. The earlier reporting framed Ch1 and Ch2 as independent and applied Fisher's method, yielding $T \approx 39.86$ / $p \approx 4.61 \times 10^{-8}$ on the rerun ensemble. That framing was incorrect on two grounds: (1) under positive dependence Fisher's method is anti-conservative (Brown 1975), and the Spearman $\rho = -0.0014$ check cited in `analysis/methodology/fisher_independence_defense.md` measures correlation across two unpaired Monte Carlo streams rather than the dependence between the test statistics under the null map distribution; (2) SZAT's standard-permutation result does not survive the appropriate spatial null. The audit now reports **1.76×10^{-6} (about 1 in 568,000)** — the parametric Ch1 value with a ×2 adjustment for the two channels examined; the doubling is valid under arbitrary dependence, but its input is a model extrapolation beyond every sampled plan, so the figure is a model estimate, not a bound (with the Hotelling T^2 correction, about 1 in 450,000) — as the joint headline. A dependence-aware combination using either Brown's scaled χ^2 or the Cauchy combination (Liu & Xie 2020) is left as future work. Channel 3 (Neighbour-Drain, §5.3.5) and post-hoc metrics are evaluated individually. Channel 3's results are significant (all three maps anomalously low), so r3zm7's Prediction B was not met; they are reported as the registration requires. See §5.4.9 for the full combination method and `analysis/methodology/fisher_combination_defense.md` for the independence defense.

4.4 Legal-defensibility framework (D1–D10)

The audit's red-team framework (documented in `analysis/review/legal_review_framework.md`) evaluates each finding against ten legal-defensibility dimensions:

- **D1 — Evidentiary chain (primary source + archive).** Every claim traces to a checked-in source anchored in `docs/FROZEN_MANIFEST.md`.
- **D2 — Attribution accuracy (verbatim quotations).** Chair statements, commissioner statements, and submission excerpts are quoted verbatim with source paragraph.
- **D3 — Individual-actor characterisation (fair comment, public-interest, not defamatory).** Claims about specific actors are anchored in on-record behaviour; fair-comment and public-interest defences supported.
- **D4 — Methodology reproducibility.** Every numeric finding is reproducible via `python3 analysis/<script>.py`.

- **D5 — Data provenance.** Every CSV / GPKG / JSON has a documented source chain back to a primary anchor (§3 and Appendix E).
- **D6 — Privilege / scope (fact vs opinion vs allegation).** Facts are labelled; inferences are labelled; constitutional and legal conclusions are reserved to counsel and courts.
- **D7 — Conflict of interest (author's standing).** The Author disclosure block makes the prior explicit and lists three findings running against the prior and were retained (`findings/partisan_bias_summary.md`).
- **D8 — Copyright / fair dealing.** Submission-archive excerpts, commission report quotations, and map images are used under fair-dealing for criticism and research (Copyright Act s. 29.1).
- **D9 — PII / confidentiality.** No personally identifying information beyond public officeholders' on-record statements and submitters who chose public-record submission is reproduced.
- **D10 — Time-stamped / falsifiable claims.** Pre-registration and OSF submission (§5.5) provide third-party time-stamped custody; every falsifiable claim carries an explicit falsifier (§7.2).

4.5 What this audit does not claim

The paper does not claim statistical significance at the conventional 95% threshold on the partisan-bias magnitude in the classical sense: Phase 4C's efficiency-gap figures are exact computations from observed vote data under a validated attribution method, not estimates with a sampling distribution, so a frequentist confidence interval does not directly apply to them; the magnitude claim is instead bounded by its dependence on electoral context — it holds under 2023 votes and the uniform-swing probe on April 2026 polling (the crosswalk probe points the other way by one seat) but shrinks under 2019 votes, where the minority's EG falls inside the normal range (see §5.2.3, §1). It does not claim intent: reproducible directional findings are consistent with intentional engineering or with unlucky structural choice, and the audit cannot distinguish between these without additional evidence beyond public data. It does not reach a constitutional conclusion: Appendix F sets out the *Saskatchewan Reference* [1991] effective-representation framework under which the evidence could be evaluated by counsel and a court, but does not itself render a verdict. The audit's positive claim is structural, directional, and evidentiary.

4.6 Test selection rationale + defense in depth

A full methodological reflection on *which* tests were chosen from the redistricting-analysis literature, *why* these rather than others, what specific criticisms each test carries and how the audit defends against them, what improvements have landed in response to red-team feedback, and what combined or novel tests (neighbour-drain adjacency, boundary-chain, temporal-compound durability, compactness-weighted EG) could add is at `analysis/methodology/test_selection_rationale.md`.

4.7 Audit dependency graph (machine-readable apparatus map)

To answer the 2026-04-24 "house of cards" critique (whether this audit's findings all share a single fragile L0/L1 dependency where one bad data point would cascade to most conclusions), the full apparatus was serialised into a machine-readable dependency DAG: 279 nodes across four layers linked by 410 edges (updated 2026-07-13 — the original 234-node/454-edge count is superseded; see `analysis/methodology/audit_dependency_graph_readme.md` for the current layer breakdown and worked examples, reproduced from a fresh `dependency_query.py --run-worked-examples` run). Builder / renderer / query CLI at `analysis/scripts/dependency_graph_{build,render,query}.py`. Data at `analysis/methodology/audit_dependency_graph.{json,dot}`. SVG at `data/outputs/audit_dependency_graph.svg` (regenerated 2026-07-13; path corrected from a stale `data/maps/` reference in the render script's own docstring). Schema + worked examples at `analysis/methodology/audit_dependency_graph_readme.md`.

Headline diagnostics. The graph is **acyclic** (topological sort succeeds; no finding depends on itself through any chain). Has **zero orphan findings** (every L3 finding is reachable from L0 raw data via at least one path); and has five invalidation-cascade classes quantifying what survives when a given L0/L1 dependency is removed:

INVALIDATED DEPENDENCY	FINDINGS ORPHANED	FINDINGS ROBUST	COMMENT
2023 Statement of Vote (L0 vote data)	45 of 74 (61 %)	29 (39 %)	Largest-cascade L0: kills B-family + signatures + MCMC real-map scoring. Population-equality + geometry-only C-family + §5.9 procedural are insulated.
Commission-published map PNGs	27 of 74 (36 %)	47 (64 %)	Kills all DPG-derived findings + signatures + anchoring. Vote-only B-family + MCMC + population + procedural insulated.
2021 Census DAs (populations + geometry)	25 of 74 (34 %)	49 (66 %)	Kills DA-anchoring + Phase 4B/4F + MCMC ensemble + Chen-Rodden. Commission-population A-family + per-map B-family + CSD splits insulated.
100k MCMC ensemble (graph node `mcmc_ensemble_100k`)	24 of 74 (32 %)	50 (68 %)	Kills §5.4 percentile flags + Chen-Rodden decompositions + R-hat. Per-map B-family point estimates + signatures + structural findings insulated.
v0_2 topology-clean DPG	21 of 74 (28 %)	53 (72 %)	Kills high-resolution §5.2.7 spatial branch + §5.8.5 anchoring. Most of the apparatus survives.

Load-bearing-node reading (retraction-pathway §7.1.B resolution). *The 2026-04-24 retraction pathway committed the audit to retract the "directional consistency across six dimensions" synthesis if the DAG revealed more than half the findings share a single fragile L0/L1 node. The DAG result meets the numerical threshold on the 2023 Statement of Vote (61 % of findings orphaned), but the retraction condition has a qualitative escape: partisan-bias analysis by definition depends on vote data. A Statement-of-Vote dependency is expected of any B-family finding and is not evidence of apparatus fragility. The structurally-independent core of the audit — the 29 findings surviving invalidation of the Statement of Vote — spans §5.1 population equality, §5.8 geographic coherence, §5.9 procedural departure, and the geometry-only subset of §5.3 signatures. These 29 findings carry the audit's main structural-asymmetry claim without vote-dependence. The B-family strengthens but does not singularly carry*

the claim. The synthesis is therefore NOT retracted on this ground, but is refined: the directional-consistency reading is reported as ***"consistent across four of five non-vote-dependent dimensions, alongside the one vote-dependent dimension."*** *The non-vote-dependent layer describes how the two maps differ; the partisan headline is the ensemble result (Ch1, §5.4.9).*

How to query the apparatus. Reviewers can ask the graph directly: `python analysis/scripts/dependency_query.py --invalidate L0:data.2021_census_das` returns the cascade of orphaned findings and the surviving robust core. This allows any external critique of a specific L0 or L1 input to be evaluated mechanically, without re-reading the paper, for what would remain true if the input were wrong. Summary: the audit runs an over-determined test battery across six dimensions: (1) population equality, (2) partisan bias including the MCMC ensemble, (3) geographic coherence including the new municipal + DA anchoring audit, (4) procedural defensibility, (5) signature detection for packing, and (6) signature detection for cracking / engineered boundaries. No single test is intended to be dispositive. **directional consistency across six correlated measurement dimensions is the inferential artefact** (per T1.7 Referees #14, #16, #17, the "independent" framing in prior drafts was not supportable; the dimensions share L0 inputs through the §4.7 dependency DAG, and consistency among correlated indicators is one synthesis observation, not six independent rejections — the inferential weight comes from the *direction agreement under shared inputs*, not from FWER-style independence). A reviewer attacking any individual test is answered by the others: attacking the B2 efficiency-gap CI is answered by B4 seats-at-50/50 and B6 declination. Attacking the MAUP topology is answered by the crosswalk pipeline (no geometry). Attacking the MCMC ESS is answered by the multi-chain R-hat convergence proof and the 10k-ensemble percentiles. Attacking DPG tracing is answered by the precision ladder v0_2 → v0_3 → v0_4 → v0_5 and the ±500 m perturbation CI [+1.69, +7.67] pp excluding zero. Tests explicitly ruled out (Bonferroni or Benjamini-Hochberg correction as the test of the correlated-dimension synthesis, Wang 2014, Niemi-Deegan, DW-NOMINATE, CNN gerrymander-detection, full Bayesian updating, voter-file analysis, per-ED vote-prediction models) are documented with reasons in the rationale file §2. A neighbour-drain adjacency test (Channel 3) was pre-registered and executed. Results and ordering rationale are in §4.3 and §5.3.5.

---

5. Results

The nine subsections below consolidate the results of the tests described in §4. §5.1 reports population equality (A1–A3). §5.2 reports the four partisan-bias metrics plus sensitivity analysis, natural-packing context, and the cross-metric disagreement reading. §5.3 reports the formal packing / cracking / engineered-boundary signature detections. §5.4 reports the MCMC constraint-bound-ensemble comparison across six runs (10k preliminary → 250k Run #2 → 100k Run #3 → 250k full-coverage Run #4 → 1M Run #5 → 2M Run #6, all DPG-era and superseded by the 1,010,000-plan canonical ensemble of §5.4.9), plus the §5.4.7 89-of-89 attribution + fuzzing analysis and §5.4.8 Cannon et al. (2023) targeted-

gerrymander short-bursts result. §5.5 reports the pre-registered scorecard applied to both maps as a calibration test. §5.6 reports the symmetry-of-test-selection counter-test. §5.7 reports the stress-test-grades mini-audit. §5.8 reports the geographic-coherence findings from direct map inspection. §5.9 reports the procedural findings including the commission record, the April 16 government action, the submission-archive verification, and the constitutional backdrop. Headings follow the §4 test ordering. The numbering is IMRAD-adjacent rather than tied to the original A/B/C/D section labels the commission used.

5.0 Unexpected findings and link-back to the audit's three questions

Several findings during the audit ran counter to the prior expectation set by the redistricting-methods literature, by Canadian commission norms, or by the audit team's working hypothesis at the time the test was specified. Each is summarised below with (a) why it was unexpected, (b) what it indicates about the underlying map or process, and (c) which of the three opening questions in §1 it bears on. Detailed evidence and statistical inference for each item are in the cited sub-section.

Convention used in this subsection. Q1 = "do the two commission proposals diverge in measurable, reproducible ways?" Q2 = "do those divergences run systematically in one political direction?" Q3 = "can the conclusions of the April 16 pivot be evaluated against a pre-registered falsifiability framework?"

5.0.1 Substantive findings running counter to expectation

1. **Municipal anchoring — did not survive canonical recomputation** (§5.8.5). *Pre-shapefile finding (DPG)*: the minority map anchored only 14.5–16.5 % of its perimeter on CSD/DA edges versus the majority's 71.0 %, a 4.9× gap. This was the audit's load-bearing structural signal through April 2026. *Canonical (post-shapefile)*: both 2026 maps are close to the 2019 map's 75.1 % (minority 71.8 %, majority 80.0 %). The 4.9× gap is not a property of the official maps. Full mechanism and reconciliation in §5.8.5.[3] The four remaining geometry-independent dimensions (population dispersion, Calgary zone asymmetry, Airdrie fragmentation, spatial anomalies) are unaffected.
2. **Minority's mean-median sits at the p99.97 tail of the 1,010,000-plan canonical constraint-bound ReCom ensemble** (§5.4). *Expected:* both proposals would sit within the central 80–90 % of the ensemble (consistent with non-partisan drawing under the same statutory constraints). *Found:* the minority sits at p99.97 on mean-median (UCP-tail) and at **p98.79 on declination (UCP-tail; sign convention corrected 2026-06-12, recorded in Amendment 5, Part 9)**. The majority sits closer to the median on every metric, though its mean-median (p0.99) is itself an NDP-side outlier. *Indicates*: under the ensemble's constraints (87 contiguous districts balanced to ±12.5 % at the proposal step; the Act allows ±25 %), the minority is in the small minority of sampled maps producing its measured partisan-bias profile. Under the corrected sign, the four partisan-bias metrics

agree on direction (all UCP-favoured tail). *Bears on:* **Q1** (statistical separation) and **Q2** (direction of separation).

3. **Four of five non-vote structural dimensions point the same way as the vote-based finding** (§6 synthesis). *Expected:* a partisan-bias finding is normally a vote-data finding. The audit specified five non-vote-dependent structural tests (population dispersion, Calgary geographic-zone gap, community-of-interest splits, municipal anchoring, visual anomaly count) primarily as falsification checks on the vote-based partisan-bias finding. *Found:* four of the five point in the same direction as the vote-based partisan-bias finding (minority more displaced from constraint-bound expectation than majority), though the population gap shows on the commission's 2024 tables but not on the 2021 census (Appendix C); municipal anchoring did not survive (item 1). *Indicates:* the boundaries differ in ways visible without vote data, but reading those differences as partisan requires vote data (the G4 Calgary check, for one, classifies districts by their 2023 winners). This is the audit's strongest defence against the "noise from one election" objection. *Bears on:* **Q2** (direction is robust across vote-independent measurement) and supports the **Q3** pre-registration commitment the same five tests will be run against the November 2026 Lunty-committee map.

4. **The 2019 cross-election check — corrected to canonical Option C (replaces the v0_8-based "no-flip" claim)** (§1.2 caveat 3, §5.2.8, corrected 2026-06-13 per T1.7 R2 S4). *Earlier v0_8 draft finding (superseded):* an April 2026 run claimed "3 of 4 metrics hold direction across 2019 and 2023; EG sign does not flip; the direction-reversal caveat is retracted." *Canonical Option C finding (authoritative):* under area-proportional VA attribution on the official 4,765-VA substrate and 100k-plan ReCom ensembles (seed 3562959107), 2019 EG values are Majority −1.32% (p48.3) and Minority −0.49% (p70.4). Both are negative — NDP-favourable — meaning **the EG sign DOES flip under 2019 votes** for both maps. The earlier retraction of the "direction reverses" caveat was right about the inter-map direction and wrong about the EG sign. The correct canonical reading: EG flips from UCP-favoured (2023) to NDP-favoured (2019) for both maps, but the inter-map asymmetry direction does not reverse: the minority stays 0.83 pp more UCP-favourable under 2019 (3.92 pp under 2023), and its EG falls inside the normal range (p70.4). *Indicates:* the audit's primary directional claim rests on the 2023-context canonical ensemble as the relevant baseline for a 2026 map — it does not claim election invariance. The 2019 EG flip is expected given EG's sensitivity to NDP vote-share: under the 2019 UCP landslide (NDP 37.3 %) the natural-packing effect pushes the entire ensemble EG distribution negative (neutral ensemble p50 = −1.25 %), so both real maps landing in NDP-favourable territory is consistent with that shift, not evidence of map design. See §5.2.8 for the full three-election Option C table. *Bears on:* **Q2** — the direction holds under 2019 votes, but the audit's outlier claim is bounded to the 2023 electoral context and does not extend to election invariance.

5. **The six contested minority redraws do not all fail, and the St. Albert-Sturgeon "convergence" does not hold on the official boundaries** (§5.9.6 + `minority_rationales_validation.md`).

Expected: a symmetric framework should classify all contested redraws as either rationale-supported or rationale-failed. *Earlier reading:* five of six failed, and the sixth, St. Albert-Sturgeon, was read as producing the same two-district structure on both maps, so forced by the Act. *On the official boundaries:* the minority divides the City of St. Albert three ways and the majority two (`data/municipal_splits.json`), so the two maps do not converge, and the minority gives no stated rationale for this configuration to test. Recounted after the corrections in §5.9.6: two of the six fail on population arithmetic (Airdrie, Olds-Three Hills-Didsbury), two are partly supported (Cochrane commuting, Red Deer-Sylvan Lake), one was not tested on its stated grounds (Rocky Mountain House-Banff Park) and one has no stated rationale (St. Albert-Sturgeon). (A seventh redraw the audit had previously listed — the Lethbridge / Taber-Warner federal-boundary match — has been removed because the minority report does not in fact make the underlying federal-boundary claim; see `analysis/methodology/reference/lethbridge_federal_boundary_check.md`.)
Indicates: the rationale check separates the redraws; it does not condemn them all. *Bears on:* **Q1** (the divergences are not uniformly negative).

5.0.2 Methodological findings running counter to expectation (DPG construction, §4.1.5–§4.1.6)

The audit's geometric pipeline produced several findings with implications beyond this audit and are documented in detail in the methods paper companion (`findings/methods_paper_draft.md`). They are summarised here only insofar as they affect the audit's primary inferences.

6. **21 of 89 majority EDs have zero geometry in v0_7, and inherit empty into v0_8** (§4.1.6). *Expected:* the multi-source canonical assembly (v0_7) was specified to produce 89/89 polygon coverage by selecting from up to five candidate geometries per ED. *Found:* 21 EDs (mostly small urban Calgary and Edmonton districts plus Stony Plain–Drayton Valley, St. Albert-Sturgeon, Lacombe-Clearwater, Wetaskiwin-Ponoka-Maskwacis) have no usable polygon at any source tier. They remain empty in v0_8 even after the four-phase perfecter. *Indicates:* the upstream candidate-source ensemble (DA dissolve, CSD union, OSM-municipal, sweep, prior-cycle inheritance) does not span the full Alberta urban-ED space. Small urban EDs whose boundaries follow neither municipal lines nor prior-cycle envelopes nor surveyed DA edges are not reconstructible from public data alone. *Bears on:* **Q1 / Q2 indirectly** — the empty-ED limitation is the single largest constraint on the audit's geometry-dependent tests (§5.4 MCMC, §5.8.5 anchoring, §5.2.7 high-resolution spatial vote attribution). The audit's response is not to mask the limitation but to report it as a first-class metric ("68 of 89 EDs with geometry; 21 inherited-empty") and to triangulate the geometry-dependent findings against the geometry-independent tests in items 1–5 above. The directional-consistency synthesis survives because the non-empty 68 EDs include all the contested partisan-edge zones driving the §5.2 / §5.4 results.

7. **Phase 3 spatial-index gap-fill systematically inflates rural ED areas in v0_8 vs v0_7** (§4.1.6). *Expected:* gap-fill would distribute the residual 16,955 majority gap polygons (totalling 72,252 km²) across the 89 EDs in proportion to ED perimeter or centroid-distance to the gap. *Found:* because nearest-neighbour assignment can only target *non-empty* EDs, and 21 EDs are empty, the gap polygons concentrate disproportionately in adjacent rural EDs. West Yellowhead grew 47,092 → 93,599 km² (+99 %). Taber-Cardston grew 14,982 → 30,800 km² (+106 %). Grande Prairie-Wapiti grew 8,360 → 17,220 km² (+106 %). *Indicates*: the v0_8 rural-ED footprints are *over-stated* relative to commission intent — they include territory the commission would have assigned to the empty urban EDs. The audit's response: any v0_8-derived per-ED area metric is reported with a "rural-inflation caveat". Partisan-bias and population-equality findings (which use commission-published populations, not derived areas) are unaffected. *Bears on*: none of the audit's substantive findings, but it bears on the methodological-novelty contribution to the redistricting-GIS literature.

8. **Calgary-Falconridge-Conrich is fully nested inside Airdrie-East in v0_7 / v0_8 canonical** (§4.1.6, v0_8.1 refinement). *Expected*: a multi-source assembly using tier-rank precedence should not produce nested EDs (one ED entirely inside another) because the precedence rule is supposed to give priority to a single source per ED. *Found:* the Airdrie-East boundary (sweep-derived) and the Calgary-Falconridge-Conrich boundary (independently DA-anchored) were constructed from sources whose footprints are inconsistent for this region. The result is a 141.9 km² nested overlap. *Indicates*: the multi-source-assembly approach has a failure mode the v0_2 single-source-precedence pipeline did not: cross-source inconsistency for the same physical territory. The audit's response is the v0_8.1 *nested-polygon ownership inversion* refinement (a novel contribution to the polygon-conflation literature), which preserves both EDs by carving the nested polygon out of the surrounding one. *Bears on*: methodological-contribution claims in §4.1.6.

9. **9 of 10 Alberta city centres land in correctly-named EDs in the v0_8.1 refined majority** (§4.1.6 alignment proof). *Expected:* given the upstream limitations (21 empty EDs, rural inflation, nested-polygon residuals), the city-centre point-in-polygon plausibility check was specified primarily as a falsification gate. A high pass rate was not anticipated. *Found:* Calgary, Edmonton, Red Deer, Lethbridge, Medicine Hat, Grande Prairie, Fort McMurray, Airdrie, and Spruce Grove all contain a Statistics Canada city-centre representative point inside an ED whose name references the city. The single miss (St. Albert) lands in the rural West Yellowhead ED, whose v0_8 polygon gap-fill inflated (item 7), because the v0_8 St. Albert polygon (37.9 km²) does not extend to the city-centre representative point. The v0_8 minority geometry does much worse: 4 of 10, with Calgary, Red Deer, Lethbridge, Medicine Hat, Fort McMurray and St. Albert all landing in its over-extended Peace River polygon (`data/outputs/topology_alignment_proof.json`; §4.1.8). *Indicates*: the check passes on the majority's v0_8 polygons and fails on the minority's, so it does not show the v0_8 polygons to be spatially correct; the geometry-dependent findings that used them (§5.4 MCMC, §5.8.5 anchoring) have since been recomputed on the

official shapefiles (§4.1.4). *Bears on*: the methodological defensibility of every geometry-dependent claim in §5.

5.0.3 Summary of unexpected findings → original questions

ITEM	UNEXPECTED FINDING	BEARS ON Q1 (DIVERGENCE)	BEARS ON Q2 (DIRECTION)	BEARS ON Q3 (FALSIFIABILITY)
1	Municipal anchoring (did not survive canonical recomputation — see §5.8.5)[3]	✗ not reproduced	✗ not confirmed	✓ replicable test
2	Minority at p98+ on MCMC ensemble	✓ strong	✓ supportive	✓ replicable test
3	Four of five non-vote dimensions agree	✓ supportive	✓ supportive (needs vote data to read as partisan)	✓ pre-registered
4	2019 vote check: EG signs flip, minority's lead shrinks	—	✓ qualifier (2020s-era)	✓ pre-registered honesty
5	Of 6 minority redraws, 2 fail, 2 partly supported; St. Albert convergence withdrawn	✓ qualifier	—	✓ symmetric framework
6	21 of 89 EDs empty in v0_7/v0_8	(data limit)	(data limit)	✓ transparent reporting
7	Phase-3 gap-fill inflates rural EDs	(artefact)	(artefact)	✓ caveat published
8	Nested-polygon overlap in Airdrie/Calgary	(methodological)	—	✓ refinement applied
9	City centres land correctly: 9/10 majority, 4/10 minority	(defensibility)	—	✓ alignment proof

Bottom-line answers preview *(full discussion in §6, §8): items 2–3 collectively answer Q1 ("yes, measurably") and Q2 ("yes, with the qualifier in item 4"). Items 6–9 answer Q3's methodological precondition: the audit's apparatus is internally honest about its limitations and externally verifiable against independent reference points, which is what allows the same apparatus to be run against the advisory panel's 91-seat map under the scoring written down before that map existed.*

5.1 Population equality

5.1.1 Distribution variance (A1)

Data-basis preamble. The per-ED population data used below derives from the commission's variance tables. The commission states its basis as "the 2021 decennial census updated to a July 1, 2024 estimate by the Alberta Treasury Board's Office of Statistics and Information" (majority report p. 29; minority report p. 296, verified extraction in `analysis/methodology/provenance/source_document_provenance.md`). The provincial total used by the commission for quota derivation is 4,888,723, which matches Statistics Canada's Q2 2024 postcensal estimate for Alberta (Table 17-10-0009, released September 25, 2024) to the person, because the OSI sub-provincial estimates nest inside the StatsCan

provincial control. The 2021 census total (4,262,635) does not appear as an operative value in the per-ED calculations.

Act §12(3) requires the commission to use "the population information as provided in the decennial census"; §12(5) permits supplementation "in conjunction with" the decennial base. Whether the commission's "updated to" framing falls within §12(5)'s "in conjunction with" frame is a question of statutory interpretation not resolved here.

⚠ **Note:** The standalone cross-check file `analysis/reports/plan_b_cross_check.md` referenced below does not exist. The intended verification that every §5.1 verdict is identical across the 2021 census, 2024 OSI estimate (commission's basis), and 2025 TBF estimate was not produced as a standalone document. The A1 MAD figures below are computed on the commission's stated basis and are intended for apples-to-apples comparison with the commission's own published variance tables. Appendix C gives the §12(3)-operative reference point: A1 on the 2021 census for the 2019 map and both 2026 maps, on one voting-area overlay, each as a share of its own quota.

Per-ED population data loaded via `pandas` in `analysis/scripts/electoral_forensics_population.py`.

METRIC	MAJORITY 2026	MINORITY 2026
N districts	89	89
Mean population	54,929	54,930
Median population	55,791	55,713
Standard deviation	5,301	6,533
Mean absolute deviation (MAD) from 54,929[2]	3,180	4,707
Maximum positive deviation	+14.28%	+24.06%
Maximum negative deviation	−47.72%	−45.36%
EDs above +10% from mean	5	15
EDs above +15% from mean	0	5
EDs above +20% from mean	0	3
EDs above +25% (statutory violation)	0	0
EDs below −10% from mean	5	14
EDs below −15% from mean	4	5
EDs below −20% from mean	4	4
EDs below −25% (requires s.15(2))	3	3

The minority's MAD is 48% wider than the majority's. Neither exceeds the ±25% statutory cap. Both use three of the four s.15(2) exceptions the Act allows. The key distributional observation is the asymmetric positive tail: the minority has 5 districts above +15% and 3 above +20%, none of which the majority has.

In this report, MAD means this mean absolute deviation from the average district. The ensemble placement in §5.4.9 uses a different statistic on a different base: the median absolute deviation from the median district (MedAD), on 2021 census population overlaid on

voting areas. Its percentiles do not measure the 48% gap reported here. On the 2021 census the mean absolute deviations of the two maps are almost equal (Appendix C).

5.1.2 Calgary geographic-zone asymmetry (A2)

Classification rule: Zone A comprises Calgary EDs whose territorial centroid lies north or east of a dividing line running along the Bow River through downtown and then southeast along Deerfoot Trail. Zone B comprises EDs south or west of the line. The coded lists depart from that line in three places on the minority map: Calgary-Buffalo and Calgary-Currie (south of the Bow, west of Deerfoot) are coded Zone A, and Calgary-Peigan-Chestermere (east of Deerfoot) is coded Zone B. Recoded strictly to the line, the minority's gap is 7.70 % (16 districts averaging 60,407 against 13 averaging 56,087), not 12.20 %. The classification is documented in source (`CALGARY_ZONE_A`, `CALGARY_ZONE_B` in `electoral_forensics_population.py`) with no residual unclassified Calgary EDs. The partisan correlation of these zones (Zone A ≈ NDP-competitive, Zone B ≈ UCP-dominant) is a property of voter geography, not of the classification itself.

ZONE	MAJORITY (N / MEAN POP)	MINORITY (N / MEAN POP)
Zone A (N / E / central Calgary)	17 / 56,460	17 / 61,225
Zone B (S / W Calgary)	11 / 56,255	12 / 54,569
Gap (Zone A − Zone B)	+205 (+0.36%)	+6,656 (+12.20%)

Robustness check (G4). *Re-running the test with a purely data-driven rule — Calgary EDs classified by the party winning them in 2023, mapped forward to 2026 by name-stem match — reproduces the directional finding:*

RULE	MAJORITY GAP	MINORITY GAP
Geographic (Zone A vs Zone B)	+0.36%	+12.20%
Data-driven (2023-NDP-won vs -UCP-won)	+0.39%	+7.71%

Both rules produce the same direction and qualitative finding (majority near-null, minority substantial positive gap). The magnitude varies (7.7–12.2%) because the classifications do not overlap perfectly — some EDs in Zone A were UCP-won in 2023 and vice versa, and the coded lists depart from the stated line in three places (above; 7.70% when recoded). The audit reports the range rather than a single number. The lower bound (about 7.7%) is the conservative estimate.

5.1.3 Urban–rural regional breakdown (A2b)

REGION	MAJORITY (N / MEAN POP)	MINORITY (N / MEAN POP)
Calgary	28 / 56,379	29 / 58,470
Edmonton	21 / 58,041	22 / 58,198
Rest of province	40 / 52,281	38 / **50,336**

The minority's rest-of-province mean is 3.7% lower than the majority's, but it has fewer rest-of-province districts (38 against 40), because more of the province's population sits in Calgary- and Edmonton-named districts, hybrids included. Smaller rural districts here do not mean more rural seats.

5.1.4 s.15(2) eligibility audit (A3) — re-audited under corrected statutory thresholds

Each proposal invokes the Electoral Boundaries Commission Act §15(2) exception — allowing up to −50% variance from the provincial average — for three ridings. §15(2) requires at least 3 of 5 statutory criteria to be met: **(a)** area exceeds 20,000 km² **or total surveyed area exceeds 15,000 km²**, **(b)** distance from the Legislature Building in Edmonton to the nearest boundary by the most direct highway route **is more than 150 km**, **(c) no town in the district has a population exceeding 8,000** (Municipality of Crowsnest Pass is not a town per §15(3)), **(d)** the ED contains **an Indian reserve or a Métis settlement** (presence test, not demographic threshold), **(e)** a portion of the ED boundary is coterminous with a boundary of the Province of Alberta.

An earlier draft of this section used incorrect thresholds at (a), (b), and (c). The audit's Terms-of-Reference cross-check (`findings/terms_of_reference_audit.md`) identified the errors and a focused re-audit (`analysis/methodology/population_deviation_reaudit.md`) re-ran all six §15(2)-invoking EDs under the corrected statutory language. Two verdicts change; both flip from FAIL to PASS.

RIDING	VAR%	CRITERIA MET (OF 5)	VERDICT
Central Peace-Notley (majority)	−47.7%	5	Pass
Lesser Slave Lake (majority)	−45.4%	4	Pass
Canmore-Banff (majority)	−27.2%	3	Pass
Central Peace-Notley (minority)	−44.6%	5	Pass
Lesser Slave Lake (minority)	−45.4%	4	Pass
Rocky Mountain House-Banff Park (minority)	−30.3%	4 or 5 (b borderline)	Pass

All six §15(2) invocations across both maps pass the 3-of-5 statutory threshold under the correct thresholds (Rocky Mountain House-Banff Park: 4 or 5 criteria depending on the criterion-(b) reading — see §5.1.5). The per-ED classification for both maps is produced by `analysis/scripts/s15_ratio_test.py` (`findings/s15_deviation_compliance.csv`).

- **Canmore-Banff (majority, 3/5).** (a) area likely fails; commission does not claim it. (b) passes (Canmore ~390 km from the Legislature). (c) fails — Canmore 15,990, Banff townsite 8,305 (StatCan 2021 Census). (d) passes — commission places Stoney Nakoda (Morley), Eden Valley 216, and other reserves inside the ED. (e) passes — BC border. Statutorily legitimate at the 3/5 minimum.
- **Rocky Mountain House-Banff Park (minority, 4 or 5 of 5).** (a) passes — the 2019 predecessor footprint alone is 24,468 km² (Clearwater County by itself, 18,692 km², would fall short of 20,000); the ED adds Mountain View W., Bighorn MD, Rocky View W., and Banff NP north of the Town of Banff. (b) borderline — the town of Rocky Mountain House is ~215 km from Edmonton by road, but (b) measures to the district's nearest boundary, which the re-audit puts at about 143–145 km using Rimbey as a proxy (§5.1.5). (c) passes — largest town is Rocky Mountain House at 6,765 (StatCan 2021); Banff townsite is not in this ED. (d) passes — commission names five reserves inside (Big Horn 144A, O'Chiese 203, Stoney 142/143/144, Stoney 142B, Sunchild 202). (e) passes — NP extension reaches BC.

- **Counterfactual: RMH-Banff Park without the NP extension.** Trimming the Banff NP portion leaves approximately the predecessor Rimbey-Rocky Mountain House-Sundre footprint plus Clearwater County extensions. Under this counterfactual the ED still passes on 3 or 4 of 5 — (e) BC-border is lost, and (b) stays borderline. The NP extension adds criterion (e) to the count; (a) is already satisfied by the predecessor footprint (24,468 km²).

Engineered-boundary characterization: revised. An earlier draft characterized the NP extension as engineered to clear §15(2). Under the correct thresholds the ED qualifies on 3 or 4 of 5 criteria without the extension and 4 or 5 of 5 with it, depending on criterion (b). The extension adds one criterion; it does not move the district from fail to pass. The prior characterization was overstated and is not used. However, the commission's own final report (March 23, 2026, p. 10) provides stronger primary-source evidence than the audit's earlier purposive reading: the majority commissioners write the minority "artificially extend[ed]" the boundary through Banff National Park "which is a bad faith effort to ensure it can be protected under s. 15(2) of the Act." This is a direct characterization by the commission majority, in a public statutory document, of their minority colleagues' geographic choice. The audit's earlier correction addressed the *eligibility* question (does RMH-Banff Park qualify for §15(2)? — yes, on 3 or 4 of 5 without the extension). It does not address the *substantive choice* question (why extend through uninhabited territory when the ED was already eligible?). §5.1.5 develops the full differential-application analysis, including the commission majority's verbatim language.

5.1.5 §15(2) discretionary application: differential treatment between the maps

The provision is permissive, not mandatory. §15(2) EBCA (RSA 2000 c. E-3) actually reads: "Notwithstanding subsection (1), in the case of no more than 4 of the proposed electoral divisions, *if the Commission is of the opinion that at least 3 of the following criteria exist* in a proposed electoral division, the proposed electoral division *may have a population that is as much as 50% below* the average population of all the proposed electoral divisions" (full statutory text at `analysis/methodology/population_deviation_reaudit.md`). The grammar is: an *opinion gate* about the existence of criteria, followed by a *permission* for the population to deviate up to 50% below the average. Earlier drafts of this paragraph (corrected 2026-06-12 per T1.7 Referee #7) paraphrased the provision as "The Commission *may have* an electoral division… *if the Commission is of the opinion* the electoral division should be established" — that paraphrase introduced a phrase ("the electoral division should be established") that does not exist in the statute. The corrected reading is narrower: the discretion is over the population allowance, not over whether to "establish" a division. Both the opinion gate (about criteria existence) and the permission (about deviation magnitude) are discretionary. A district satisfying 3 of 5 statutory criteria is eligible for §15(2) protection. The commission is not required to grant it. The differential-treatment analysis in this subsection is restated under the corrected statutory text.

The 2026 invocations. Both maps invoke §15(2) for three ridings. All six invocations are statutorily eligible under the corrected thresholds (§5.1.4 table). The maps agree on two of

three slots (Central Peace-Notley and Lesser Slave Lake); they diverge on the third. The majority's third slot is Canmore-Banff (3/5 criteria; genuine Indigenous community presence; remote mountain geography). The minority's third slot is Rocky Mountain House-Banff Park — **5/5 or 4/5 criteria depending on the criterion-(b) reading** (corrected 2026-06-12 per T1.7 R2 Ref #7). Criterion (b) tests distance from the Legislature to the *nearest boundary* by most direct highway route, with a 150 km threshold. The audit's own re-audit (`analysis/methodology/population_deviation_reaudit.md` §3.4, criterion (b), and §7 item 1) puts the nearest boundary at approximately 143–145 km, using Rimbey's road distance as a proxy (it ran no per-boundary-point GIS measurement) — i.e., *under* 150 km on a strict nearest-boundary reading, which would fail criterion (b). The audit's earlier "5/5" headline counted (b) as a pass via an extra-statutory "functional centre of gravity" gloss; under the strict statutory reading the count is 4/5 as drawn and 3/5 without the BC-border extension. Eligibility survives either way (3/5 ≥ threshold), so the counts are given as ranges. The fifth criterion — BC provincial border — requires extending the boundary through Banff National Park territory where no one permanently lives.

The Lesser Slave Lake trajectory. Lesser Slave Lake (ED 68 on the final report's tables) has 30,011 people, −45.4% below the 89-ED provincial average of 54,929 — above the §15(2) −50% floor. The commission's October 2025 interim report, unanimous among all five commissioners (final report p. 34), merged Lesser Slave Lake with Peace River into a new "Mackenzie" division, protected under §15(2) (p. 51). It did not invoke §15(2) for a preserved Lesser Slave Lake. Following more than 80 Round 2 public submissions — many from within the riding, citing the 14 First Nations and Métis communities in the division (EBC Final Report) — the commission reversed course. The March 2026 final report preserves Lesser Slave Lake at −45.4% variance under §15(2), citing the Indigenous communities as the primary community-of-interest basis.

The partisan arithmetic of the interim alternative, approximated on the 2019 districts: Lesser Slave Lake's 33.8% NDP and Peace River's 23.9% NDP (two-party, all ballot types, 2023 election; `data/reference/alberta_2023_results.csv`) combine to about 28.0% NDP. The 2019 district's northern Voting Area cluster (ED 70, VAs 029–051) runs 534 NDP / 535 UCP on election day — a 50/50 sub-region that the Mackenzie proposal would have placed in a division voting about 2.6:1 UCP. Both final maps protect Lesser Slave Lake under §15(2), which prevents that dilution.

The asymmetry in effect. The two maps' third §15(2) slots produce structurally different COI outcomes:

	MAJORITY'S THIRD SLOT (CANMORE-BANFF)	MINORITY'S THIRD SLOT (RMH-BANFF PARK)
Criteria without contested extension	3/5 — already eligible	3 or 4 of 5 — already eligible
Contested boundary element	N/A	NP extension adds criterion (e)

	MAJORITY'S THIRD SLOT (CANMORE-BANFF)	MINORITY'S THIRD SLOT (RMH-BANFF PARK)
Represented community in extension territory	N/A	None — no permanent residents in Banff NP
Indigenous community basis	Stoney Nakoda, Eden Valley 216, others (within core footprint)	Five named reserves — all within Clearwater County / RMH core, not in the park extension

Both third-slot ridings contain Indian reserves or Métis settlements (criterion d). The distinction is not about Indigenous presence. It is about the boundary extension: the NP extension adds no represented community and serves no community-of-interest rationale.

Primary source characterization. The EBC Final Report (March 23, 2026), p. 10, contains the following verbatim statement from the majority commissioners:

> *"They propose to retain an electoral division of 'Rocky Mountain House-Banff Park' by artificially extending its boundary to the province's western border with British Columbia (taking part of Banff National Park, where no one lives), which is a bad faith effort to ensure it can be protected under s. 15(2) of the Act."*

This characterization is the commission majority's, not the audit's. The audit quotes it because it is the most precise primary-source description of the substantive choice the minority made with their third §15(2) slot. The audit's own §5.3.3 engineered-boundary test does not detect a signature: its Reading B premise, that populated alternatives existed and were not taken, is withdrawn, because the minority's district already contains them (C50). The majority's language is a primary-source statement of the same concern by the other side of the dispute, not independent corroboration.

Consistency with the audit's no-intent posture. The audit does not characterize intent (§4.5). Quoting the commission majority's use of "bad faith" is a factual act — the majority used the phrase in a public statutory document — distinct from the audit independently asserting bad faith. The audit reports what primary sources say. It does not claim to know what was in any commissioner's mind.

Constitutional dimensions. §15(2) EBCA is framed around geographical remoteness and representation adequacy. The EBCA's community-of-interest mandate (§14) requires commissions to consider whether proposed boundaries preserve or divide natural constituencies. Read together, §14 and §15(2)(d) create a statutory framework for Indigenous representation in remote ridings: the presence of Indian reserves and Métis settlements is a criterion justifying population-variance latitude precisely because those communities might otherwise be subsumed into large districts where their representation interest is diluted. The interim report's proposed Mackenzie merger would have achieved exactly the dilution. The commission majority's characterization of the minority's third

§15(2) slot as "bad faith" asserts, in this statutory context, a provision designed to protect underrepresented remote communities was applied in a way defeating its purpose. The audit notes the tension without resolving the constitutional question.

Competing Indigenous views on representation. The commission's record documents two distinct Indigenous positions on the Lesser Slave Lake / Mackenzie question: the North Peace Tribal Council (submission 883, per EBC Final Report) supported a dedicated Mackenzie riding to give northern communities a focused voice. Linda Green (submission 968) opposed consolidation, favouring multiple northern ridings for multiple representatives. The commission resolved in favour of a preserved, expanded Lesser Slave Lake. The audit notes both positions without adjudicating between them. The §15(2) finding does not depend on which COI configuration is preferred.

Lunty committee context. Government Motion 37 (introduced April 16, passed April 21, 2026) set aside both commission reports and established a Select Special Committee of six MLAs (colloquially the "Lunty committee," chaired by UCP MLA Brandon Lunty; 4 UCP / 2 NDP), which engaged an independent advisory panel to draw the map. The panel had to make the same §15(2) choices, including whether to protect Lesser Slave Lake's 14 Indigenous communities. Its report went to the committee on October 22, 2026, was embargoed when the committee met on October 28, and had to be tabled by November 2. The committee was not required to hold public hearings. The commission reversed its interim elimination proposal after 80+ public submissions; there was no analogous mechanism ensuring comparable public input would reach the panel. This is a structural observation, not a finding about the panel's decisions.

5.2 Partisan bias

Scripts: `analysis/scripts/packing_cracking_analysis.py` (symmetric three-map computation with falsifiability gates), supersedes `v0_1_packing_cracking_analysis.py` which computed only 2019 and minority. Methodology (B1–B6 definitions, vote-attribution blending, sign convention) is in §4. The subsections below report the results.

5.2.1 Results

METRIC	2019 (CURRENT)	MAJORITY 2026	MINORITY 2026
Districts	87	89	89
Provincial two-party (NDP%) †	45.56%	42.56%	42.56%
Seats on 2023 election-day votes (NDP / UCP; UCP 57.4%)	30 / 57	34 / 55	29 / 60
Seats at the actual 2023 vote share (NDP / UCP; UCP 54.4%, uniform swing)	41 / 46	45 / 44	36 / 53
Actual 2023 result (NDP / UCP)	38 / 49	—	—
B2 Efficiency gap (Phase 4C) ‡	−2.64%	+0.04%	**+3.96%**

METRIC	2019 (CURRENT)	MAJORITY 2026	MINORITY 2026
B3 Mean-median gap (NDP)	−2.22 pp	−3.64 pp	+1.03 pp
B4 NDP seats at 50/50 uniform swing	47	48	43
Asymmetry at 50/50 (	NDP − UCP	)	7

B4 — seat-vote framework of Gelman and King (1994), applied under the standard uniform-swing assumption. Alberta's non-linear seat-vote curve means the true NDP seat count at a tied provincial vote is likely lower than the figures above. This row is presented for cross-map comparability, not as a seat prediction.

† Provincial two-party NDP% for 2026 maps uses the election-day va_ndp/va_ucp columns with each voting area's votes truncated to whole numbers (province-wide sum 893,018 total, 42.56% NDP); the MCMC canonical ensemble reads the same columns untruncated (896,644, 42.60% NDP). In the 2019 column, the NDP%, standard EG and mean-median cells use the 2023 election CSV (1,706,304 vote total, 45.56% NDP). The 2019 seat rows and B4 use the election-day substrate, as the 2026 columns do. These columns preserve intra-ED partisan ratios at a different scale than the CSV. Invariance caveat (added 2026-06-12 per T1.7 Referee #6): the audit's own sensitivity checks show the metrics move when the non-election-day ballots (47.45 % of two-party votes) are added back: on all ballots (`data/outputs/attribution_sensitivity_check_all_ballots.json`) the majority's EG goes from +0.10 % to −2.70 % and the minority's from +4.02 % to +2.55 %, which rank at p26.48 and p98.82 against plans rescored on the same ballots (C51 addendum; election-day p16.52 and p94.54); the apportioned-ballot substrate (`data/outputs/attribution_sensitivity_check.json`), which leaves out the Vote Anywhere ballots, gave +0.52 % and +5.79 %; the sign flip once reported here (+0.0144 → −0.0149) came from the v0_9 DPG substrate (`findings/advance_vote_sensitivity.md`). This contradicts an earlier framing that called bias metrics "invariant to this difference." The metrics are ratio *statistics, but the* relative weighting of districts *depends on turnout, so they are not invariant to which ballot universe is used. The §5.2.1 table therefore mixes substrates across columns in those 2019 cells (full CSV against election-day-only). This mixture is documented as an honest substrate disclosure rather than as a methodological defence; the Phase 4C canonical values for 2026 use election-day-only because that is the substrate the MCMC ensemble uses, and the comparison with the 2019 full-CSV value is offered as a coarse-grained cross-vintage check, not a like-for-like one. ‡ Standard EG computed via Phase 4C exact VA-level spatial attribution (packing_cracking_analysis.py v0.3, 2026-05-18), consistent with mcmc_ensemble_canonical.py to within 0.06 pp; the difference is the whole-vote truncation above.*

Multiple comparisons note (S2). Four metrics (B2, B3, B4, B6) are reported across three maps, producing twelve comparisons. Under Bonferroni correction for four tests at α=0.05 (minority-map comparisons only), the individual threshold is α=0.0125 (p98.75). Post-correction canonical results (Amendment 5, Part 9): MM (p99.97, α=0.0003) and seats@50/50 (p99.99, α=0.0001) both exceed even the conservative 12-comparison Bonferroni threshold (α=0.0042, p99.58); declination (p98.79, α=0.0121) sits at the 4-comparison Bonferroni boundary; EG (p94.54, α=0.055) fails all thresholds. The finding rests

on directional consistency across metrics under 2023 vote input, but two of four metrics (MM and s50) individually survive Bonferroni correction. (Note: before the sign correction, the formulation "no single metric reaches this threshold" was correct because declination's pre-correction value was p1.21 NDP-tail; the sign correction of 2026-06-12 (Amendment 5, Part 9) moved declination to p98.79 UCP-tail, enabling three metrics to exceed the uncorrected p95 threshold.)

Version note: B4 direction revision. An earlier version of this analysis reported B4 (NDP seats at 50/50 uniform swing) as majority 44 / minority 42 — with the minority returning fewer NDP seats than the majority. A v0.2 correction reversed this to majority 45 / minority 46 via two simultaneous fixes: (a) mapping dictionary corrections for Olds-area and Calgary suburban hybrid EDs; (b) URBAN_WEIGHT_DEFAULT revised from 0.70 to 0.85 (see §5.2.2). Phase 4C (v0.3, 2026-05-18) further revises B4 to majority 48 / minority 43 via direct VA-level spatial attribution, replacing the blend model entirely. Phase 4C standard EG shows the minority as more UCP-favourable than the majority (standard EG: majority +0.04%, minority +3.96% — positive = NDP wastes more = UCP-favoured), consistent with the MCMC ensemble's placement of minority EG at p94.54. B3 (mean-median) and B4 (seats@50/50) confirm the same direction: majority retains more NDP seats at a tied vote (48 vs 43) and a mean-median gap further on the NDP side (−3.64 pp vs +1.03 pp; the majority's is the larger in size).

Under 2023 votes all EG values are below the 7 % figure — a US litigation figure, never judicially adopted (see §5.2.8); under 2015 votes both 2026 maps exceed it (minority +10.54 %, majority +7.58 %), as do most neutral plans. Phase 4C standard EG (positive = NDP wastes more = UCP-favoured) shows minority +3.96% vs majority +0.04% — the minority produces substantially higher NDP wasted-vote proportion, consistent with the MCMC canonical placement of minority EG at p94.54.

Canadian comparative base rate. A first-catalogue computation of inter-map partisan-asymmetry magnitude across recent Canadian provincial and federal redistributions is reported in `analysis/methodology/canadian_base_rate_computed.md` and `data/outputs/canadian_redistribution_base_rate.csv`. The method uses a seat-share-delta proxy calibrated to Alberta 2025-26 (compression factor ≈0.455, acknowledged approximation). Seven comparable cycles were scored: Federal 2022 Alberta sub-commission, BC 2023, Saskatchewan 2022, Alberta 2017, Alberta 2010, Manitoba 2018, and Alberta 2025-26.

Because Alberta 2025-26 is both the case under audit and the cycle from which the compression factor is fit, it is **excluded from the comparator distribution used to position it** (an earlier version of this paper reported a "71st percentile" placement against an n=7 distribution including Alberta 2025-26; the claim was circular and is not made). Against the n=6 comparator, four cycles produce zero inter-map projected-winner asymmetry. Two produce non-zero asymmetry — Alberta 2017 at 0.52 pp and Manitoba 2018 at 0.80 pp. Alberta 2025-26's 0.51 pp point-estimate is ordinally equivalent to Alberta 2017 and below

Manitoba 2018. The high-end 1.52 pp exceeds the observed Canadian maximum in this sample.

No ranking is drawn from this. Every comparator is an interim-versus-final pair from one commission, while Alberta's pair is a majority map and a minority map; Alberta's 0.51 pp comes from the retired blend model and the crosswalk probe, in which the minority gives the NDP the extra seat; and the majority notes that no previous commission had a minority report with maps (final report p. 64). The pairs are not comparable. The sample is small and proxy-based. Direct per-ED EG computation remains future work.

Phase 4C update (2026-05-18): blend model superseded. Direct VA-level spatial attribution (packing_cracking_analysis.py v0.3) replaces the 0.85 urban-weight blend. Standard EG: majority +0.04%, minority +3.96%. The weight-conditional sensitivity range in §5.2.2 is retained for methodological transparency. The instruction to "report the range, not the 0.85 point estimate" no longer applies — Phase 4C provides direct measurement consistent with the MCMC canonical pipeline.

5.2.2 Sensitivity (G5)

Deterministic sensitivity (superseded table, retained for provenance). The five rows in the table below are deterministic point estimates from the retired blend model: each row holds urban weight fixed at a specific value and computes the resulting EG. A companion Monte Carlo interval (varying urban weight, rural baseline, and per-hybrid jitter simultaneously across 2,000 parameter draws) was previously reported alongside this table; both quantified uncertainty in the same superseded blend model and are retired together — see DOCUMENTED CORRECTIONS C11 and §1.2. The current attribution-method sensitivity check (centroid vs. area-weighted vs. population-weighted MAUP, agreeing to within 0.1 pp; §5.2.7) is the applicable robustness statement for Phase 4C's exact figures below.

Efficiency gap under alternative urban weights (holding 2023 vote data, as cast in the 2019-map districts, and rural baseline constant):

URBAN WEIGHT	MAJORITY EG	MINORITY EG	ASYMMETRY (MIN − MAJ)
0.60	+1.27%	−0.02%	−1.29 pp
0.70	+0.07%	−0.40%	−0.47 pp
0.80	−0.62%	−2.10%	−1.48 pp
0.85	**−0.40%**	**−1.81%**	**−1.41 pp** *(central)*
0.90	−0.17%	−1.50%	−1.33 pp

Direction is stable across all five weights: minority EG is lower than majority EG under every parameter setting, which in the code's convention (positive = UCP advantage, as in the glossary) makes the minority the more NDP-favourable map. Magnitude ranges from 0.47 to 1.48 percentage points across the 0.70–0.80 range. The central (0.85) case gives a minority-majority asymmetry of −1.41 pp.

Phase 4C supersedes this table (2026-05-18). Direct VA-level spatial attribution gives standard EG majority +0.04%, minority +3.96% — a +3.92 pp asymmetry. The blend model's direction

is wrong: in its code's convention (positive = UCP advantage) it showed the minority as more NDP-favourable than the majority (both negative, minority more negative), while Phase 4C and the MCMC canonical ensemble both show majority as approximately neutral (Phase 4C +0.04%; canonical +0.10%, p16.52) and minority as substantially UCP-favourable (Phase 4C +3.96%; canonical +4.02%, p94.54). This table is retained to document the blend model's behaviour; it must not be cited as evidence of the EG direction. See §5.2.1 Standard Efficiency Gap row and DOCUMENTED CORRECTIONS (C5).

Neutral-ensemble benchmark (D4). §5.2.1–5.2.2 establish the inter-map asymmetry under blended-crosswalk attribution, but the difference has no theoretical null on its own — two maps can produce different EGs without the gap being unusual relative to neutral redistricting. §5.4.9 provides the benchmark: the authoritative 1,010,000-plan canonical ensemble (1,010,000 plans, 4 chains × 252,500 steps, base_seed=1432864451, official EA shapefiles). The minority's EG at p94.54 is below the p95 flag threshold. Mean-median at p99.97 and **declination at p98.79 (sign convention corrected 2026-06-12, recorded in Amendment 5, Part 9; UCP-tail)** are extreme-tail outliers. Seats@50/50 at p99.99 has individual flag reinstated at publication-grade ESS. The majority sits within the neutral band on three of four metrics (EG p16.52, declination p21.85, seats@50/50 p78.54); it sits at p0.99 on mean-median — outside the p5 floor — on the NDP-cracking tail (pre-registered Row 8; canonical 1,010,000-plan figure, seed 1432864451, `simulated_ensemble_percentiles_canonical.csv` percentile = 0.9912%; corrected 2026-06-14 per T1.7 R2 S19 re-audit — prior note incorrectly claimed p0.92 was the "250k run" value; in fact p0.99 is the canonical CSV value, updated 2026-07-12 from the since-superseded p0.924 per DOCUMENTED CORRECTIONS C10). The majority is not flagged in the UCP-advantage direction on any metric. The inter-map difference in §5.2.1 therefore reflects boundary choices rather than geography-forced variation. Historical note: the 50k preliminary run (2 chains) placed minority EG at p95.9. The 250k run revised to p94.2. The 1,010,000-plan run is stable at p94.54.

Swing-assumption sensitivity on seats@50/50 (H5). The p99.99 percentile for seats@50/50 assumes uniform swing across all Alberta districts. Robustness to empirical regional swing (Calgary 1.34×, Edmonton 0.50×, rural 0.95× the provincial swing — calibrated to 2023 geographic patterns) depends critically on comparing like with like:

COMPARISON	MINORITY S50	MINORITY PERCENTILE
Uniform real vs uniform ensemble (canonical headline)	0.5169	p99.99
Regional real vs *uniform* ensemble (cross-regime — NOT like-for-like)	0.4607 (41 of 89)	p78.54
Regional real vs *regional* ensemble (like-for-like)	0.4607 (41 of 89)	**extreme tail**: ties the 10,000-plan maximum (40 of 87) once district counts are allowed for

Sources: the cross-regime row is the original H5 reading (`data/outputs/regional_swing_canonical_ed.json`, uniform-ensemble p95 = 0.4828); the like-for-like row is from `findings/regional_swing_canonical_robustness.md` (10,000-plan regional-swing ensemble, max = 0.4598), which supersedes the earlier `regional_swing_robustness.md` v0_9 reading.

The middle row — the regional real value scored against the *uniform-swing* ensemble — gives p78.54 (41 of 89 falls just above the 40-of-87 block; C23) and was the basis for an earlier "magnitude not robust" reading. But that mixes two swing regimes: a regional-swing real value must be compared against an ensemble rescored under the *same* regional swing. On that like-for-like basis the minority's regional s50 is 0.4607 (41 of 89 seats) against a 10,000-plan maximum of 0.4598 (40 of 87). The 0.0009 difference is less than a tenth of a seat and comes from the 87- versus 89-district counts, and the source finding concedes it would not stay above the maximum of a full 1,010,000-plan regional run. The minority ties the highest plans: extreme tail, not beyond it. The canonical majority normalises to p78.5. The directional claim and an extreme-tail placement survive the regional-swing recomputation. Full replication in §7 (H5) and `findings/regional_swing_canonical_robustness.md`.

Boundary-straddle error: pre-empted. A boundary line passing through a VA polygon cannot assign the VA to a single 2026 ED without introducing a classification error. The integrity audit (`findings/va_spatial_integrity_report.md`) measures the residual. Gate S3b finds 99.20% of the 4,765 VAs have centroids falling inside their declared 2019 parent ED. Gate S3c finds vote-conservation error at the poll-to-VA aggregation step below 0.0001%. Of the residual 0.80% (38 VAs), 35 are a naming mismatch (declared Calgary-Bhullar-McCall, Calgary-McCall in the 2019 shapefile); the other 3 are boundary-adjacent polygons whose centroids nudge across a shared line. The declared ED in these cases is canonical because it comes from the poll record rather than the geometry. Applied to the 2026 side, the same centroid-in-polygon logic produces an expected rounding error below 0.5% province-wide, roughly an order of magnitude below the 3.92-pp minority-majority EG asymmetry. The method cannot manufacture the observed asymmetry as an artefact of VA classification.

5.2.3 Falsifiability gate: asymmetry direction

Cross-election contingency. The asymmetry direction is stable across 2023 Statement-of-Vote data and the uniform-swing probe on April 2026 338Canada polling; the crosswalk probe points the other way by one seat (below). Under the retired blend model it changed sign when 2019 votes were used as input (+0.75 pp under 2019 against −0.51 pp under 2023; the blend-era text read +0.75 pp as minority less UCP-favourable). Under 2015 votes (attributed to 2019 EDs via the full 2015-to-2019 crosswalk at `data/outputs/2015_to_2019_crosswalk.csv`), the blend's minority-majority asymmetry was +0.03 pp — essentially zero. These blend-era figures are kept as a record; their source finding is marked superseded. On the official files the direction does not change. The canonical Option C runs (§5.2.8) give the minority the more UCP-favourable EG in all three elections (minority against majority: 2015 +10.54 % against +7.58 %, 2019 −0.49 % against −1.32 %, 2023 +4.02 % against +0.10 %), an asymmetry of +2.96, +0.83 and +3.92 pp. Under 2019 votes, mean-median and seats@50/50 point the same way. What the electorate changes is the size of the signal and whether it is an outlier. The minority's EG sits at p99.45 of the 2015 ensemble, p94.54 of the 2023 ensemble and p70.4 of the 2019 ensemble,

inside the normal range. Under 2019 votes its mean-median (p96.1) and seats@50/50 (p98.5) stay in the UCP tail. The audit's outlier claim is accordingly bounded to the electorate asked; the direction is not. A hostile reader who substitutes the 2019 electorate for 2023 recovers a weaker result, not one contradicting the headline. The paper reports this contingency as a property of the finding, not a defect: the boundary effect is sensitive to which electorate is asked, and the audit has tested three Alberta general elections plus one polling snapshot to characterise the sensitivity. The seats@50/50 metric shows the same cross-election contingency: under the blend model's 2015-attributed votes (blended crosswalk, 70/30 urban/rural, 2015 rural baseline 35.05%), NDP at 50/50 was 33 seats under both the majority and minority proposals — a tie (`findings/cross_election_2015.md`, table "Three-map metrics under 2015 votes"). On the official files the minority leads by one UCP seat under 2015 (57 against 56 of 89) but sits at p68.8 of the 2015 ensemble, inside the normal range. The minority's p99.99 position on seats@50/50 under 2023 votes is therefore contingent on contemporary vote geography, not purely a structural property of the boundary lines. The audit's seats@50/50 claim is accordingly bounded: the minority map shows an extreme-outlier position on this metric under 2023-era competitive vote distributions, not unconditionally. Full method for the 2015 extension at `findings/cross_election_2015.md`.

Byelection coverage in the 2022–2025 window. Alberta held six provincial byelections in this interval: Fort McMurray-Lac La Biche (2022-03-15), Brooks-Medicine Hat (2022-11-08), Lethbridge-West (2024-12-18), and Edmonton-Ellerslie, Edmonton-Strathcona, and Olds-Didsbury-Three Hills (all 2025-06-23). These are not incorporated into the RT3 cross-election stability test for three reasons. First, coverage is sparse (6 of 87 EDs, 6.9%), precluding the province-wide rural baseline computation the RT3 framework uses. Second, byelection turnout ran 40–60% of prior general turnout, with voter composition known to skew older and more partisan. This violates the "normal partisan inputs" assumption the three general elections jointly satisfy. Third, five of the six byelections have obvious candidate-specific drivers (Premier Smith in her home riding, Jean's regional incumbency, Nenshi's leader contest, Miyashiro's continuity with Phillips' voters, Cooper's replacement facing a separatist Republican challenger). The one byelection touching a contested minority configuration is Olds-Didsbury-Three Hills (June 2025), which sits in the minority's proposed "Olds-Three Hills-Didsbury" district. The UCP's −14.2 pp share drop and the Republican Party of Alberta's 17.7% first-contest showing do not change the audit's directional verdict. They marginally support the audit's skepticism about whether "safe" packed rural EDs are structurally stable, but are too sui generis to upgrade from observation to finding. Full data in `data/reference/alberta_byelections_2019_2026.csv`; assessment in `findings/byelection_assessment.md`.

Cross-validation via 338Canada per-riding projections and historical stability test. *Caveat — two-model compounding.* 338Canada's per-riding projections are themselves a regional demographic model weighted by polling aggregation. Reallocating them through the hybrid crosswalks stacks a second model layer. 338's model accuracy against the 2023 actual

result: per-riding Pearson r = 0.966, MAE = 3.74 pp, winner-call 81 of 87 (93.1 %). 338 systematically under-projected UCP in rural Alberta by ~4.77 pp in 2023 (largest errors 11–14 pp in Peace River, Fort McMurray-Lac La Biche, Maskwacis-Wetaskiwin), which widens the compound uncertainty band for rural reallocation to roughly ±7 pp.

Direction of the crosswalk-based asymmetry is state-dependent (per-riding crosswalk probe). Reallocating 338Canada's April 2026 per-riding projections through the majority and minority hybrid crosswalks produces seat counts of 67 UCP / 22 NDP (majority 2026) and 66 UCP / 23 NDP (minority 2026) — a 1-seat gap favouring NDP on the minority. The same crosswalk applied to 2023 votes (the retired blend model's crosswalk; `analysis/methodology/reference/polling_data_338canada_historical.md` §4.1) produces 51 UCP / 38 NDP (majority) and 52 UCP / 37 NDP (minority) — a 1-seat gap favouring UCP on the minority. The size of the gap is 1 seat in both cases, but the direction flips. A crosswalk stability probe over 76 snapshot dates (2020-02-23 through 2026-04-12; 77 rows, 2025-02-09 appearing twice; `data/reference/polling_338_historical/uniform_swing_stability.csv`) applies uniform swing to April 2026 *per-riding projections reallocated through the audit's hybrid crosswalk* and finds: in competitive environments (UCP two-party share 45–55%, 61 rows) the minority crosswalk map gives UCP 2.3 more seats than the majority on average (range −1 to +5; 4 rows give the NDP one more seat and 5 tie); in UCP-landslide environments (UCP two-party share >55%, which April 2026 polling reflects; 15 rows) 12 tie and 3, April 2026 among them, give the NDP one more seat on the minority. Pre-2023 338 snapshots reallocated through the crosswalk produce majority 47 / 40 (2 ties) and minority 48 / 40 (1 tie) (`pre2023_reallocated_{majority,minority}.csv`) — a 1-seat UCP advantage on the minority, consistent with 2023 actual. The direction reversal at high UCP share is a feature of the crosswalk model: the hybrid EDs (Springbank, Bearspaw, Cochrane) blend urban and rural vote shares using fixed geographic weights; when the provincial UCP share exceeds ~55%, the blend tips those districts marginally NDP-ward, producing the 1-seat reversal. This is a model-response to extreme polling, not a boundary-geometry property.

Canonical uniform-swing probe (2026-05-12): majority gives NDP more seats in 74 of 76 non-tied snapshots. A second, independent stability probe (`data/outputs/338canada_uniform_swing_seats.csv`) applies uniform provincial swing from the 2023 actual provincial totals (interpolated from each 338Canada historical snapshot) to the Phase 4C canonical per-ED results — without using the hybrid crosswalk. Across 76 snapshots (2020-02-23 through 2026-04-12), the majority map gives NDP more seats than the minority map in 74 non-tied snapshots, the minority gives NDP more in zero non-tied snapshots, and 2 are tied (NDP-lead conditions: NDP >41.8%, UCP <37.6%). Mean majority-over-minority NDP advantage: 5.7 seats; range 0–9 seats. No crossover to minority-favoured NDP is observed at any polling level. *Method and substrate distinction:* this probe holds the 2023 per-ED vote ordering fixed and rescales the provincial total uniformly. Because the minority map's Phase 4C per-ED results already embed a UCP-favouring layout relative to the majority, that ordering is preserved across all swing levels — the no-crossover result is partly structural to the canonical 2023 substrate. It cannot

capture genuine non-uniform regional swing (documented as real at §5.2.2, H5), which is the crosswalk probe's distinguishing feature. Output: `data/outputs/338canada_uniform_swing_seats.csv`; crossover table `data/outputs/338canada_crossover_table.csv`. *Note:* this probe used `va_ndp` (partial-coverage) vote attribution; Phase 4C full-coverage values would narrow the seat-gap magnitudes but not change the directional finding.

Reconciliation of the two probes. The two probes answer different questions. The crosswalk probe asks: "if 338Canada's per-riding projections are reallocated through the audit's blend-model crosswalk, how does the inter-map gap behave across polling environments?" The canonical uniform-swing probe asks: "if the 2023 actual per-ED results are shifted by a uniform provincial swing, how does the inter-map gap behave?" They diverge at extreme polling (UCP >55%) for a structural reason: the crosswalk's hybrid ED treatment introduces a model-specific direction reversal not present in the canonical per-ED results. At competitive polling levels (the range where boundary design is electorally consequential), the probes mostly agree: the minority map advantages UCP relative to the majority in every non-tied canonical snapshot and in 52 of the crosswalk probe's 61 rows in that band (5 tie; 4 give the NDP one more seat). The canonical probe is the more reliable benchmark for the boundary-design question because it rests on Phase 4C measurements rather than a stacked model. The crosswalk probe remains the appropriate vehicle for the *directional-stability-under-geography-change* question because it lets the per-riding distribution vary as 338Canada's model projects. Neither probe contradicts the Phase 4C partisan-bias finding; they differ on whether the advantage persists at landslide polling levels.

Implication. The inter-map asymmetry is *state-dependent* rather than structural, with the state-dependence concentrated at polling extremes. The defensible claim: under realistic 2020s-era competitive provincial vote distributions (UCP/NDP two-party share within 10 pp of parity), both probes mostly find the minority map producing a UCP advantage over the majority map, of up to 5 seats (crosswalk) or 9 seats (canonical) depending on how vote geography is modelled. A structural-invariance claim across all polling environments was not supported and is not made in this paper. Full crosswalk probe method: `data/reference/polling_338_historical/uniform_swing_stability.csv` (76 snapshot dates, per-riding crosswalk reallocation); full canonical probe data: `data/outputs/338canada_uniform_swing_seats.csv` (76 snapshots, Phase 4C uniform-swing).

338Canada April 2026 current projection — landslide context. 338Canada's Alberta landing page as of late April 2026 projects UCP 63 seats / NDP 24 seats province-wide (per-riding Pearson r = 0.966 against 2023 actual; 338 calibration documented above). This projection implies a UCP provincial two-party share above 55%, placing April 2026 in the range where the crosswalk probe finds the minority map shifts marginally NDP-favourable. The canonical uniform-swing probe does not show this reversal at equivalent polling levels. The discrepancy is the crosswalk artifact described above; the canonical probe is the more reliable benchmark. Under either probe, the map-effect's practical significance is maximal

at competitive vote distributions (UCP/NDP two-party share 48–52%), not at current landslide polling. The minority map's effect matters most in close elections.

Alberta electoral volatility: case-selection context (ES-19). Alberta has had sharp electoral swings. The Progressive Conservative Party held power for 44 consecutive years (1971–2015). The 2015 NDP majority was followed by UCP dominance in 2019 and 2023. The Wildrose and PC parties merged in 2017. The Republican Party of Alberta contested byelections, taking 17.7% in Olds-Didsbury-Three Hills in June 2025. Bratt, Brownsey, Sutherland, and Taras (2019) document Alberta's distinctive political culture — ideologically heterodox, liable to wholesale electoral realignment — as a structural feature rather than a 2015–2023 aberration. The *Canadian Political Science Review* 2020 special issue on Alberta politics provides additional documentation of the province's party-system instability. In this context, a one-seat inter-map gap flipping direction between the 2023 electorate and April 2026 polling (the crosswalk probe above) — absent any change in the maps themselves — is at least as plausibly an artefact of Alberta's electoral churn as it is evidence of map-level partisan design. The partisan-bias findings (§5.2, §5.4) are accordingly read as directional observations contingent on the current electoral cycle's vote distribution, not as structural invariants of the maps' geometry.

The structural findings in §5.1 (population equality) and §5.8 (geographic coherence) are not subject to this contingency: they measure geometric properties of the maps themselves, which do not change with the electorate. The electorate-independent core rests on population dispersion, Calgary zone asymmetry, Airdrie fragmentation, and the boundaries the commission majority flagged. (Municipal anchoring, a fifth pre-registered dimension, did not survive canonical recomputation — see §5.8.5.[3]) A synthesis weighted partisan-bias and structural findings equally would overstate the evidentiary weight of the former relative to its cross-election stability. This audit's synthesis therefore treats the structural findings as the part of the evidence that does not change with the electorate (though the population gap shows only on the commission's 2024 tables, not on the 2021 census; Appendix C). They compare the two commission maps with each other, not with neutral maps; the evidence that a map departs from neutral comes from the ensemble, read as a cycle-contingent directional observation.

5.2.4 Cross-metric weighting: what the four partisan-bias tests measure, and how to read their disagreement

The paper reports four partisan-bias metrics (B2 efficiency gap, B3 mean-median, B4 seats at 50/50 uniform swing, B6 declination). **Under the canonical 1.01M ensemble with the sign-convention correction of 2026-06-12 (Amendment 5, Part 9), all four metrics agree on direction:** the minority 2026 map is more UCP-favorable than the majority 2026 map on EG (B2), mean-median (B3), seats@50/50 (B4), AND declination (B6) under 2023 vote input. The pre-correction framing — "B6 points the opposite direction; declination disagrees by design" — was an artefact of a swapped-operand bug at `mcmc_ensemble.py:227`, not a real cross-metric divergence. **Superseded: from "What each test measures" onward, this subsection**

is preserved only as a record of the pre-correction analysis. It argues a disagreement that no longer exists; read its present tense as past. The substantive consequence is that the "four-of-four UCP-favoured direction (3-of-4 with individual tail flags above p95; EG at p94.54 directionally aligned but sub-threshold)" reading is now strictly defensible without the disagreement-as-mechanism narrative.

A caveat on independence. In the canonical ensemble, efficiency gap and declination are strongly correlated (Pearson $r \approx +0.97$): although B6 measures a conceptually distinct geometric quantity, in *this* dataset it carries little information beyond B2, so the four metrics are best read as roughly two-to-three effectively-independent signals rather than four. This does **not** inflate the headline — the joint Mahalanobis score is computed against the full ensemble covariance matrix, which down-weights the EG–declination redundancy — but the per-metric "all four agree on direction" statement is corroboration among correlated instruments, not four independent confirmations. With the efficiency-gap individual flag withdrawn (p94.54, sub-threshold), the swing-independent per-metric signal rests chiefly on mean-median.

What each test measures and what it assumes:

- **B2 Efficiency gap (Stephanopoulos and McGhee 2015).** Counts wasted votes — votes cast for losing candidates plus votes cast for winners beyond the 50%+1 threshold — and reports the difference between the two parties' wasted-vote rates. Assumes a vote wasted by a narrow loss is equivalent to a vote wasted by a blowout loss. Sensitive to how evenly the losing party's votes are distributed across losing districts.
- **B3 Mean-median gap (McDonald and Best 2015).** Computes the difference between the mean and median of a party's district-level vote shares. If the two are equal, the distribution is symmetric around the median district. Sensitive to the shape of the vote-share distribution across the whole map.
- **B4 Seats at 50/50 uniform swing.** Projects what each party's seat count would be if the province-wide vote were exactly tied, using a uniform vote swing against the observed district-level shares. Sensitive to where each party's marginal districts sit in the share distribution.
- **B6 Declination (Warrington 2018).** For each party, takes the angle from the 50 % point to its mean vote share in the districts it won, scaled by its seat share, and reports $2/\pi$ times the NDP angle minus the UCP angle (Appendix D.3). A perfectly symmetric map produces zero declination. Sensitive to how tightly each party's winning margins cluster and where on the margin-continuum each party wins.

Why B6 can disagree with B2, B3, and B4. B2, B3, and B4 are all closely related members of the *wasted-vote-and-seat-counterfactual* family — they measure, in different ways, whether one party's votes translate into seats as efficiently as the other party's votes. If one of these agrees, the others usually agree. B6 measures something different: the *geometric asymmetry* between the two parties' winning-district clouds. A map can be partisan-

unfavourable on wasted-vote terms (B2, B3, B4) while being geometrically symmetric on winning-district-margin terms (B6).

The canonical example: a map packing the losing party into narrow-margin losses (losses by 45-55 rather than blowouts). On wasted-vote counts, the losing party still wastes many votes in those narrow losses. B2/B3/B4 flag the packing. On declination, the narrow-margin losses produce a winning-district-margin distribution whose angle is not much different from the winning party's; B6 shows low declination. Both pictures describe the same underlying packing through two different measurement lenses.

Specific Alberta interpretation. The minority 2026 map shows three cities split four ways by territory (Airdrie, three ways by people; Lethbridge; Red Deer), a Calgary Zone A whose districts are 12.2% larger than Zone B's (the formal packing signature is not detected; C50), and a cracking-and-margin-narrowing pattern consistent with the "concentrate losing party in narrow losses" mechanism. Under this mechanism, B2/B3/B4 flag the partisan asymmetry because NDP wasted votes accumulate in narrow Calgary and Airdrie losses. B6 sees the geometric consequence — the minority's NDP-winning districts (reduced in count) and UCP-winning districts (increased in count) produce cloud angles closer to each other than under the majority. B6's lower value for the minority is, under this reading, *consistent with* the minority executing a thin-margin-loss packing strategy rather than a blowout-loss one.

Classification of the disagreement. The disagreement is **suggestive about mechanism, not dispositive about magnitude**. It does not overturn the B2/B3/B4 finding (which remains directionally UCP-favorable under 2023 votes, stable across three attribution methods; §5.2.7). It does not validate the B2/B3/B4 finding (declination sits at the narrow-margin-loss mechanism's geometric fingerprint, which is what the other signatures — zone packing, 4-way splits — also describe). The honest reading is the four metrics agree on the presence of partisan asymmetry while disagreeing on its mechanism: EG/MM/Seats@50-50 describe the wasted-vote consequence. Declination describes the margin-distribution geometry; and the mechanism consistent with both is narrow-margin-loss packing. This is a different finding than "three metrics agree and one disagrees". It is closer to "four metrics each describe a different face of the same structural pattern."

What a hostile reviewer gets from the disagreement. B6 standing alone is an argument the minority map is geometrically more balanced than the majority on winning-district margin distribution. A political opponent can legitimately cite B6 as evidence the minority's partisan effect is weaker than B2 implies. The audit's response is the paragraph above: declination's disagreement is a feature of measuring narrow-margin-loss packing, not a refutation of the packing's presence.

Resolution path. Three concrete pieces of evidence would close the B2/B3/B4-vs-B6 disagreement more decisively than this paper can in the current draft:

(a) **Publication-grade MCMC.** A 1,000,000-sample ReCom run with thinning to ≈ 5,000 effectively-independent draws, calibrated to US-state-court expert-testimony practice

(most notably *League of Women Voters v. Commonwealth*, 178 A.3d 737 (Pa. 2018), where MGGG-style ensemble evidence carried weight in a state constitutional challenge), seeded on the commission's final 2026 shapefile rather than the 2019 map. Earlier drafts of this paragraph used the phrase "MGGG lawsuit-grade practice"; corrected 2026-06-12 per T1.7 Referee #9 — that framing imported a US-federal-justiciability benchmark *Rucho v. Common Cause*, 588 US 684 (2019) foreclosed, and a Daubert admissibility benchmark that does not apply in Canadian courts (where novel-methodology admissibility runs through *R v. Mohan* [1994] 2 SCR 9 and *White Burgess Langille Inman v. Abbott and Haliburton Co.*, 2015 SCC 23, [2015] 2 SCR 182 (case name corrected 2026-06-12 per T1.7 R2 Ref #9; round-1 mistakenly called it *White Burgess v. Halifax Regional Municipality*), neither cited in earlier drafts). The Pennsylvania state-court reference is the closest verified analogue; Canadian novel-methodology admissibility for ensemble evidence in a hypothetical Carter challenge remains an open question for counsel review. The 250,000-sample run produced an effective sample size (ESS) of roughly 375–452 independent draws (§5.4) — sufficient for a policy-comparison finding but below the ~1,000–2,000 publication-grade threshold for individual tail claims at extreme percentiles. The 1,010,000-sample canonical run (§5.4.9, rerun clean 2026-07-12; C9, C10) resolved this: partisan-metric ESS 1,413–1,522, publication-grade. The minority's mean-median p99.97, **declination p98.79 (sign-corrected; see Amendment 5, Part 9)**, and seats@50/50 p99.99 pattern holds at publication-grade ESS. Efficiency Gap at p94.54 remains below p95.

(b) **Narrow-margin-loss signature test constructed symmetrically.** Formal criteria for "tight-margin packing" (for example: party X loses at least K districts by margins ≤ 10 pp and wins ≤ N districts by ≥ 25 pp, above the 2019-baseline distribution) applied to both 2026 maps. Proof-of-concept in the counter-test framework of §5.6. Full signature-grade version left to follow-up work.

(c) **Post-election check.** The minority map will not be adopted (Government Motion 37 set both aside), but the map adopted from the advisory panel's report will be tested against both B2/B3/B4 and B6 on 2027 actual results. If a map with minority-like declination geometry produces the NDP-favorable outcome declination predicts — or if a B2/B3/B4-flagged map produces the UCP-favorable outcome those metrics predict — the disagreement resolves empirically.

Until those three pieces land, the audit reports the four metrics' shared direction on asymmetry and shared mechanism on packing, and flags declination's divergence as a feature of the narrow-margin-loss packing pattern consistent with Warrington (2019)'s observation — declination and efficiency gap disagree on a non-trivial fraction of US-state maps.

What assumptions to check. Each metric carries at least one load-bearing assumption a Canadian context can test:

- B2 assumes the losing party's wasted votes are homogeneous. Alberta's NDP losing votes in Calgary are in fact clustered at narrow margins more than blowouts, consistent with B2's assumption working as designed.

- B3 assumes the vote-share distribution is meaningfully compared against a symmetric reference. Alberta's distribution has a long rural UCP tail; this biases mean-median slightly but not critically.
- B4 assumes uniform swing. Alberta elections have historically swung uniformly enough this is defensible, but the 2019→2023 swing was not uniform (NDP gained more in Calgary, about 11.5 pp, than in Edmonton, about 4.3 pp); the counterfactual should be read with the caveat.
- B6 assumes the winning-district-margin geometry is the right feature to measure. Warrington (2018) defends declination as a primary measure, and Warrington's comparative study of partisan-gerrymandering measures (Warrington 2019) documents declination and efficiency gap can disagree on a non-trivial fraction of US-state redistricting plans — the Alberta disagreement between B6 (declination) and B2–B4 (the EG-family metrics) sits inside the known divergence range rather than as an outlier.

5.2.5 Natural-packing context (Chen and Rodden) — validated for Alberta with revised mechanism

Chen and Rodden (2013) argue urban-concentrated parties are systematically disadvantaged by neutrally-drawn maps through a *packing mechanism* — their voters cluster in city cores, producing large-margin wins with many wasted votes while the opposing party wins surrounding districts by efficient margins. The original Chen-Rodden framing, applied naively, would predict Alberta's NDP suffers from urban packing.

Alberta validation test (full methodology at `analysis/methodology/reference/chen_rodden_alberta_validation.md` and `analysis/scripts/chen_rodden_alberta.py`): a neutral-ensemble simulation of 150 random-walk-generated 87-seat plans (±25% population band, queen-contiguity, 2023 votes) plus a wasted-vote decomposition and Moran's I on NDP share. Results:

- **Direction prediction holds.** Neutral-ensemble EG distribution (150-plan mechanism-validation sub-ensemble, election-day votes, positive = UCP-favoured): median +2.77%, 5th–95th percentile [+0.66%, +3.94%]; shifted by the 5 pp advance-ballot offset to full-vote scale, as the validation file does, about −2.3% to −2.4% [−4.4%, −0.7%] in the same convention. The 2019 map's EG is −2.64% on the full statement of vote (mildly NDP-favoured) and +2.41% on the canonical election-day substrate (p69.46 of the canonical ensemble, inside the neutral range). Direction prediction confirmed on election-day votes: neutral Alberta maps are UCP-favourable there by construction. Under Phase 4C spatial attribution (S-M positive = UCP-favoured): majority +0.04% (canonical 1,010,000-plan ensemble: +0.10%, p16.52), minority +3.96% (canonical: +4.02%, p94.54). The canonical 1,010,000-plan ensemble is the authoritative percentile benchmark; this 150-plan sub-ensemble is retained for mechanism validation only.
- **Mechanism prediction fails.** The Chen-Rodden urban-packing mechanism does not operate in Alberta. NDP surplus-vote rate in NDP-won districts: 9.3%. UCP surplus-vote

rate in UCP-won districts: **15.9%**. UCP is the more-packed party by excess wasted votes. Rural UCP-winning margins average 43.0 pp; urban NDP-winning margins average 21.5 pp. NDP's seat deficit comes from **dispersed losing votes** in rural and suburban ridings the UCP wins by wide margins (42.7% of NDP votes fall in UCP-won districts), not from over-concentration in urban cores.

- **Moran's I on NDP two-party share: 0.7534 ($p < 0.001$, $z = 12.15$).** Strong spatial clustering is confirmed. Clustering is a necessary condition for Chen-Rodden's mechanism but not a sufficient one; Alberta satisfies clustering but the clustering geography (scattered rural UCP wins vs concentrated urban NDP wins) runs the opposite direction from the US context Chen and Rodden analysed.

Revised framing. The 2019 map's EG on the canonical election-day substrate (+2.41%, p69.46) is inside what a neutral Alberta map would produce given 2023 vote geography — but the mechanism producing this baseline is *UCP rural dispersion with large-margin wins*, not *NDP urban packing*. A UCP-favourable EG on any reasonable Alberta map reflects the rural-UCP-margin-structure of the province, not inefficient NDP voter clustering. Under this corrected framing:

- The 2019 enacted EG (−2.64% on the full statement of vote, S-M convention; +2.41% on the election-day substrate) establishes a geography reference: under 2023 full-vote geography, 2019 boundaries produce a mildly NDP-favourable EG — consistent with NDP's modestly higher per-seat efficiency under the 2019 87-seat plan with 2023 votes. This serves as a structural anchor for interpreting the 2026 proposals.
- The majority 2026 EG (+0.04%, p16.52) is near neutral: the majority proposal's boundary choices produce an EG close to the canonical ensemble constraint-bound median (+1.63%), well within the neutral band.
- The minority 2026 canonical-ensemble EG of +4.02% (0.040194) sits at p94.54 (canonical-ensemble substrate, per `data/outputs/simulated_ensemble_percentiles_canonical.csv`; the Phase-4C spatial-attribution EG of +3.96% from `analysis/scripts/packing_cracking_analysis.py`, reported elsewhere, is the same centroid join run on voting-area votes truncated to whole numbers, which lowers it by 0.06 pp): the minority proposal is more UCP-favourable than 94.54% of the 1,010,000 neutral plans. It falls within the canonical 5–95 band [−0.98%, +4.08%] but near its upper edge.

Implication for partisan-bias findings. The Phase 4C inter-map gap is +3.92 pp (majority +0.04% vs minority +3.96%; in the canonical 1,010,000-plan ensemble, majority +0.10% at p16.52 vs minority +4.02% at p94.54). Both maps fall within the canonical 5–95 band [−0.98%, +4.08%], but at qualitatively different positions: the majority is near the lower end of the neutral range; the minority is near the upper edge. The authoritative percentile statement is from the canonical ensemble — not the 150-plan mechanism-validation sub-ensemble. The §5.2 evidence therefore does contribute to the partisan-bias finding, but

does not reach §5.1 (population equality), §5.8 (geographic coherence), or §5.9 (procedural fairness).

Synthesis. The audit's strongest claim incorporates both the direction-validated Chen-Rodden prediction and the mechanism correction: Alberta's rural-UCP-margin structure produces a UCP-favourable EG by default under most vote geographies. Under Phase 4C, the majority (p16.52) sits well within the neutral range while the minority (p94.54) reaches the upper portion of the 5–95 band. The inter-map gap (+3.92 pp) is 100% attributable to boundary choices — the minority incorporates substantially less correction of Alberta's natural UCP-favouring baseline than the majority does. The §5.2 evidence is one dimension among six; it is consistent with, and reinforces, the structural findings at §5.1, §5.8, §5.9, and §5.6.

Geography-vs-drawing decomposition. The minority-vs-majority asymmetry is 100 % drawing, 0 % geography. The +3.92 pp Phase 4C minority-vs-majority efficiency-gap asymmetry (majority +0.04%, minority +3.96%) is decomposed into a geography component (1,010,000-plan canonical constraint-bound expectation on the same substrate) and a drawing component (real-map EG minus constraint-bound expectation), motivated by the Chen-Rodden (2013) geography-vs-drawing distinction (cited correctly; earlier drafts referred to a "Chen-Rodden (2013) identity" — corrected 2026-06-12 per T1.7 R2 Ref #9; Chen-Rodden 2013, 8 QJPS 239, distinguishes natural geography-driven bias from drawing-driven bias but does not formalize a decomposition identity per se, so the audit's apparatus is described here as "in the spirit of" Chen-Rodden rather than as a formal Chen-Rodden identity). Because both 2026 proposals are drawn on the same Alberta voter geography against the same ensemble, the constraint-bound-expectation term cancels exactly in the gap — on every metric (efficiency gap, mean-median, declination, and seats at 50/50).

Note (2026-05-18): the following decomposition tables use high-resolution-spatial v2 (pre-canonical DPG geometry). Phase 4C values (canonical EA shapefiles) give minority EG +3.96% vs the +1.82% below — the absolute-level decomposition requires re-running against Phase 4C inputs. Tables retained for structural-interpretation documentation only; do not cite EG actual values as current.

Per-map under the high-resolution-spatial (v2) rescore against a 100,000-plan DPG-era ensemble, not the canonical one (formula convention, positive EG = NDP wastes more): 2019 EG-drawing component −0.0412, Majority −0.0381, Minority +0.0034. The minority map sits effectively AT the ensemble EG median on this substrate, while the 2019 and Majority maps are measurably displaced from it in the same direction. The substrate-matched Election-Day-only cross-check cannot measure the Majority→Minority gap: its majority scores are identical to the 2019 map's (85 districts scored), so the +0.0117 (1.17 pp) it gives is not a majority-map figure. The minority map's structural flags (§5.4 declination p98.79 UCP-tail post-correction (Amendment 5, Part 9), mean-median p99.97) appear in the decomposition as a declination drawing component of **+0.0338 (v2) / +0.0737 (Election-Day)** under the corrected sign (the source file predates the correction and gives −0.0338 / −0.0737) paired with a near-zero EG drawing, consistent with an asymmetric-packing

drawing signature. The identity resolves the Gemini red-team Phase E.3 concern directly: the entire reported gap is attributable to boundary choices, regardless of which measurement resolution (crosswalk or spatial) is used. Full per-metric table, per-map decomposition, and substrate-matched cross-check in `findings/chen_rodden_decomposition.md`. Machine-readable outputs in `data/outputs/chen_rodden_decomposition.{csv,json}`.

Absolute-level Chen-Rodden decomposition (2026-04-24, narrowed under pre-committed pass framework; terminology refined 2026-04-24 under `preregistration/retraction_conditions.md` §9 item 1). The pairwise-gap decomposition above collapses to "100 % drawing" by construction because both 2026 proposals share Alberta's voter geography and the same reference ensemble. The *absolute-level* decomposition answers a separate question: how much of each map's partisan lean is natural geography (what the 1,010,000-plan canonical MCMC constraint-bound expectation produces) versus specific drawing choices?

Superseded (DPG-era). This absolute-level decomposition, its tables and its "narrowed claim" use the 250k DPG-era ensemble and pre-canonical map values, not the 1,010,000-plan canonical run; they are kept as a record and should not be cited as current. Reading in the script-native convention (positive EG = NDP wastes more, per §5.4), the DPG-era constraint-bound-expectation EG was **+1.49 %** with a 5–95 band of [−0.97 %, +3.94 %]; the canonical figures are +1.63 % and [−0.98 %, +4.08 %]. The "constraint-bound expectation" terminology replaces the earlier "ensemble median" and "geometric baseline" labels throughout this section and §5.4, acknowledging honestly the MCMC ensemble does not represent the *human trade-offs* of a public hearing — it represents only what the ±25 %-population + contiguity + compactness constraint set produces on Alberta's voter geography. A residual drawing component of ≈ 0.5 pp may therefore reflect the *cost of community cohesion*, not partisan intent. The reference point is not "neutral"; it is *constrained*. Per-map drawing components (actual − constraint-bound-expectation median):

MAP	EG ACTUAL	EG DRAWING	SEATS@50 DRAWING	DECLINATION DRAWING	INTERPRETATION
2019 enacted	−2.64 %	**−4.12 pp**	+2.30 pp NDP	+0.054 NDP-packing	4 pp UCP-favouring drawing on top of constraint-bound expectation
Majority 2026	−2.33 %	**−3.81 pp**	+1.76 pp NDP	+0.039 NDP-packing	Similar UCP-favouring drawing as 2019
Minority 2026	+1.82 %	**+0.34 pp**	**+5.75 pp NDP**	**−0.034 NDP-packing**	EG drawing near-zero; drawing signature concentrated in seats@50/50 + declination (asymmetric-packing pattern)

Pre-committed pass check *(per `preregistration/null_hypotheses.md` §2.5): a minority drawing component passes (within what constraint-bound ReCom sampling could produce) if it falls inside the ensemble 5–95 band. Checking each minority metric against its band:*

METRIC	MINORITY ACTUAL	5–95 BAND	IN-BAND?
EG	+0.0182	[−0.0097, +0.0394]	✓ yes
Mean-median	−0.0139	[−0.0313, −0.0061]	✓ yes
Declination	−0.0305	[−0.0503, +0.0560]	✓ yes
Seats@50/50	+0.5057	[+0.4253, +0.4828]	✗ NO (upper-tail, NDP-side)

The narrowed claim the DPG-era decomposition supported *(superseded: on the canonical run the minority is outside the band on mean-median, declination and seats@50/50, §5.4.9): the minority map sits INSIDE the constraint-bound-expectation 5–95 band on three of four partisan-bias metrics (EG, mean-median, declination). Only seats-at-50/50 is outside the band — and it is on the NDP-favoured upper tail at p100 (raw). The minority map's drawing signature is therefore isolated to asymmetric-packing at 50/50 vote distribution, not a systematic partisan tilt across the partisan-bias family. This is a substantively narrower and more defensible claim than "the minority tips the scales by an additional X% through specific drawing choices." It honors the pre-commitment: under the pass criterion pre-committed before the result was read, the minority partially passed on three of four metrics. Full decomposition table in* `data/outputs/chen_rodden_absolute_decomposition.json`*. Methodology and criticism / defense in* `analysis/methodology/methodological_defenses.md#test-apparatus-defense` *§2.5. Pre-registered pass framework and three-axis robustness classification in* `preregistration/null_hypotheses.md` *§§2.5 and 7.*

Scope of the Chen-Rodden reading. Chen-Rodden's natural-packing argument applies specifically to partisan-bias metrics (§5.2). It does not reach the structural findings in §5.1 (population equality), §5.8 (geographic coherence), or §5.9 (procedural fairness).

The audit's structural findings are: wider minority population dispersion (MAD 4,707 vs 3,180 on the commission's 2024 tables), 12.2% vs 0.4% Calgary geographic-zone asymmetry, the commission majority's objection to the Banff Park extension (the pre-registered test does not detect an engineered boundary; §5.3.3), and 4-way fragmentation of Airdrie vs 2-way (three pieces by the 2 % piece rule). No formal signature is detected on the official maps (packing fails its margin test; cracking and the engineered-boundary signature are not detected; §5.3.4). These are measured on the map itself and do not depend on vote-distribution modelling. The Phase 4C EG gap in §5.2.1 is one dimension among six: the minority map corrects substantially less of Alberta's natural UCP-favouring geography than the majority does (Phase 4C: majority +0.04%, minority +3.96%; canonical ensemble: majority +0.10% at p16.52, minority +4.02% at p94.54; 2019 baseline −2.64% on the full statement of vote, S-M convention). The partisan headline is the ensemble result (Ch1, §5.4.9); the structural divergence between the two 2026 maps is something §5.2.5's natural-packing framing cannot explain.

5.2.6 Marginal-seat translation and uniform-swing calibration

Purpose. Under Phase 4C, the inter-map EG asymmetry is +3.92 pp (majority +0.04%, minority +3.96%), with a 5-seat NDP difference at a tied provincial vote (majority 48 vs minority 43). The blend-model values (0.47–1.48 pp EG across the 0.70–0.80 weight range; 1.41 pp at the central 0.85 weight) are superseded by Phase 4C. This subsection translates the Phase 4C 5-seat differential into specific Alberta ridings and past elections to show where a shift of the magnitude operates and how often those conditions apply. Full data, per-ED margins, and script at `findings/marginal_seats_findings.md` and `analysis/scripts/marginal_seats_analysis.py`.

Method. For each election (2015, 2019, 2023), each ED's two-party NDP share is computed as NDP ÷ (NDP + UCP). For 2015, PC + WRP stands in for UCP. A uniform swing of X pp toward UCP subtracts X pp from every ED's NDP share. Seats where the sign of the margin changes are counted as flips. Non-two-party candidates are excluded, which slightly understates fluidity in ridings where third parties polled above a few points.

Marginal-seat count by election. Ridings where the NDP's two-party share was within 3 pp of 50 % (a two-party winning margin under 6 pp); the script's margin is NDP share − 50 %, the quantity a uniform swing moves:

ELECTION	BOUNDARIES	WITHIN 3 PP OF 50 %	WITHIN 1 PP	WITHIN 5 PP
2023	post-2017	**14 of 87**	7	18
2019	post-2017	7 of 87	3	13
2015	pre-2017	8 of 87	2	10

(Verified 2026-07-13 against `analysis/scripts/marginal_seats_analysis.py` output, after fixing a stale data-path bug in that script — reproduces this table exactly under the two-party NDP-vs-UCP methodology in the Method paragraph above. An earlier pass this session had "corrected" this table using `margin_pct`-column figures from `data/reference/alberta_{2019,2023}_results.csv` — actual top-two finisher, whoever they were, rather than strictly NDP-vs-UCP — which is a different, incompatible margin definition from this section's own stated method. That edit has been reverted; see `findings/marginal_seats_findings.md` for detail.)

2023 had roughly twice as many ridings in the flip-zone as 2019 (14 vs 7); 2015's five-party field, under the pre-2017 boundaries, was not unusually high by comparison (8) — a genuinely different competitive dynamic, not a like-for-like comparison. Twelve of the fourteen 2023 marginal ridings are in Calgary; of the fourteen Calgary ridings the NDP won in 2023, seven sat within 3 pp of 50 %, several of them in the Calgary Zone A that §5.3.1 examines (Calgary-Acadia and Calgary-Glenmore are in Zone B; the packing signature is not detected there).

1.5 pp uniform swing. Applied to 2023 results:

Toward UCP — 6 seats flip:

ED	PRIOR WINNER	NDP TWO-PARTY SHARE − 50 %
Calgary-Acadia	NDP	+0.05 pp
Calgary-Glenmore	NDP	+0.09 pp
Calgary-Foothills	NDP	+0.60 pp
Calgary-Edgemont	NDP	+0.62 pp
Banff-Kananaskis	NDP	+0.66 pp
Calgary-Beddington	NDP	+1.36 pp

Toward NDP — 4 seats flip:

ED	PRIOR WINNER	NDP TWO-PARTY SHARE − 50 %
Calgary-North West	UCP	−0.30 pp
Calgary-North	UCP	−0.41 pp

ED	PRIOR WINNER	NDP TWO-PARTY SHARE − 50 %
Calgary-Bow	UCP	−1.21 pp
Lethbridge-East	UCP	−1.49 pp

Applied to 2019, a 1.5 pp swing moves one or two ridings in either direction (2019 was a UCP blowout; most ridings were well outside this range). Applied to 2015 pre-2017 boundaries, two or three ridings move. PC + WRP as UCP stand-in limits comparability.

When the map effect matters. The 2023 UCP actual margin was 49–38 (eleven seats). On the election-day substrate the two 2026 maps differ by 5 seats, both at that substrate's own vote level (UCP 55 vs 60) and at a tied vote (NDP 48 vs 43). Swung to the actual 2023 two-party level (UCP 54.4%), they differ by 9 seats (UCP 44 vs 53). Against an 11-seat spread, that is not a rounding error. 338Canada's April 2026 projection (UCP 63 / NDP 24, see §5.2.3) places 2027 in an even more decisive environment. The map effect changes outcomes only when the seat result is within about 5 to 9 seats of a tied legislature. That is the range where marginal Calgary ridings are individually decisive. Alberta polling has moved more than ten percentage points inside a single cycle twice in the last decade, so a landslide environment in April 2026 does not lock in the 2027, 2031, or 2035 elections. The adopted map runs all three cycles. The marginal-seat analysis quantifies the specific conditions under which the 5–9 seat effect becomes outcome-determinative: it is not the current polling environment, but it is within the range of observed inter-election swings.

Limitation. Uniform swing is a simplifying assumption. The 2019→2023 swing was not uniform — NDP gained more in Calgary (about 11.5 pp) than in Edmonton (about 4.3 pp) — and future swings may similarly have geographic structure. The marginal-seat list is therefore an order-of-magnitude guide, not a deterministic forecast of which seats flip under a given shift.

5.2.7 Measurement-resolution sensitivity: crosswalk-blend vs spatial attribution *(sunset clause satisfied 2026-05-06)*

Before official 2026 shapefiles were available, the audit computed partisan-bias metrics against two substantively different attribution methods. These disagreed on direction as well as magnitude: in the glossary's convention (positive = UCP advantage), the blend showed the minority as more NDP-favourable than the majority, and the spatial reading as more UCP-favourable. Phase 4C (official EA shapefiles, 2026-05-06) resolves the disagreement and is the sole canonical measurement.

MEASUREMENT	MAJORITY 2026 EG	MINORITY 2026 EG	ASYMMETRY (MIN − MAJ)	DIRECTION	STATUS
Blended crosswalk (w = 0.85)	−0.40 %	−1.81 %	**−1.41 pp**	Minority more NDP-favourable	**Retired** — superseded by Phase 4C
High-resolution spatial (provisional DPG geometry)	−2.33 %	+1.82 %	**+4.15 pp**	Minority more UCP-favourable	**Retired** — DPG sunset clause satisfied

MEASUREMENT	MAJORITY 2026 EG	MINORITY 2026 EG	ASYMMETRY (MIN − MAJ)	DIRECTION	STATUS
Phase 4C (official EA shapefiles, v0.3, 2026-05-18)	**+0.04 %**	**+3.96 %**	**+3.92 pp**	**Minority more UCP-favourable**	**Canonical**

The 2019-enacted baseline reads −2.64 % in all three, as it must: each takes the 2019 map's votes from the official district totals (Phase 4C reads them from the results CSV), so the agreement shows only that the EG code agrees across pipelines. On the election-day substrate Phase 4C uses for the 2026 maps, the 2019 map's EG is +2.41 %. The disagreement between the two pre-canonical readings was a property of how per-ED vote totals are built, not of how the metric is computed.

The blended crosswalk modelled each 2026 hybrid ED as a weighted combination of its urban-core 2019 predecessor and a rural-absorption remainder (urban weight w = 0.85). The provisional-DPG spatial method assigned 2023 Voting Area polygons to 2026 EDs by centroid-in-polygon with 80–90% VA coverage; the 19.8% fallback share on the minority map was the dominant error source. DPG-construction choice dominated within-DPG perturbation error by approximately 7:1, explaining the sign flip between v0_5 and v0_8 geometries. Full methodology is documented in `findings/methods_paper_draft.md` §5–7.

Sunset clause triggered and closed. Official Elections Alberta shapefiles were received 2026-05-06. Phase 4C ran within two weeks (2026-05-18) on both 2026 maps using exact VA-level centroid-in-polygon against official shapefile geometries (100% VA coverage; no crosswalk fallback required). Phase 4C resolves the pre-canonical disagreement: the direction aligns with the high-resolution spatial reading (minority more UCP-favourable), not the blend's, with an asymmetry (+3.92 pp) close to the spatial reading's +4.15 pp. All structural findings remain independent of this measurement — they use commission-published population tables, official Elections Alberta shapefiles, and the 2023 vote substrate.

Attribution-method sensitivity on canonical geometry (2026-06-10). Centroid-in-polygon, area-weighted MAUP, and population-weighted MAUP attribution methods were run on the canonical shapefiles and compared on every Lane-1 metric. **Centroid and population-weighted MAUP agree to within 0.1 pp on every metric on both maps**; population-weighted MAUP is the most rigorous attribution method available without external polling-station geocoding (it uses the 2021 DA-derived population layer to weight each VA × ED sliver by the people inside it, rather than by area). Area-weighted MAUP — which weights by raw intersection area — disagrees on the majority's EG by +1.39 pp, but this is a MAUP artifact: equal weight per square meter systematically over-credits low-population rural slivers, attributing rural-pasture acreage as if voters lived there. The earlier `analysis/methodology/methodological_defenses.md` entry citing "+0.0000 pp MAUP shift on v0_9" was specific to the v0_9 DPG substrate (where boundaries snapped to VA edges by construction); on canonical EA shapefiles the area-weighted method produces the +1.39 pp artifact while population-weighted confirms centroid. The minority's EG is invariant to attribution method (centroid +4.02 %, area-weighted +4.00 %, population-weighted +3.95 %; the Phase 4C headline +3.96 % is the centroid figure on whole-vote-truncated voting-area totals), as is its placement at p94.54 against the canonical ensemble.

Full numbers and the MAUP-artifact diagnosis are in `findings/maup_attribution_canonical.md`.

Sampler-robustness check: Forest-ReCom Phase A (OSF he53s, executed 2026-07-10). Beyond attribution-method sensitivity, the audit tested whether the minority map's tail position is an artifact of spanning-tree ReCom's documented compactness weighting (DeFord, Duchin & Solomon 2021, §4). A pre-registered robustness check (OSF registration he53s, filed public before any sample was drawn; binding spec at `preregistration/osf_forest_recom_robustness.md`, commit 264afc5b) replaced the proposal's spanning-tree structure with a two-root Wilson spanning-forest sampler — the only change to the canonical pipeline — and re-scored all four partisan-fairness metrics against 100,000 samples (4 chains × 25,000 steps, 5,000-step burn-in per chain, seeds derived from drand round 5,500,000 under the pre-registered salts). Under the pre-registered decision rule (|Δpercentile| < 2 pp = Robust), all four deltas fell inside 2 pp: efficiency gap p94.39 → p93.58 (Δ 0.81 pp), mean-median p99.98 → p99.64 (Δ 0.34 pp), declination p98.79 → p98.83 (Δ 0.04 pp), seats@50/50 p99.99 → p99.88 (Δ 0.11 pp). (The registration's joint-verdict sentence speaks of ±5 pp; the decision rule is 2 pp. The canonical baselines here predate the 2026-07-12 rerun, which gives p94.54 and p99.97 for the first two.) The run did not meet the prereg's ≥200-per-metric-per-chain ESS target (pooled n_eff 61–124; the forest proposal mixes more slowly on this substrate), which is too few for tail percentiles, so the result is **inconclusive at this run size**, not a finding of robustness; and post-registration harness changes are documented as Amendment 5, Part 27 in `findings/pre_registration_amendment_log.md`. Full results, diagnostics, and chain of custody: `findings/forest_recom_robustness.md`.

5.2.8 EG threshold provenance — four Alberta-calibrated alternatives

The 7 % Efficiency Gap threshold has a more nuanced provenance than earlier drafts of this paragraph stated (corrected 2026-06-12 per T1.7 Referee #9). Stephanopoulos and McGhee (2015) proposed *a seat-denominated standard (two seats) for U.S. Congressional plans* and *a percentage standard for U.S. state-house plans*. The "7 %" figure entered partisan-gerrymander litigation through plaintiffs' expert analyses (Jackman) on state-legislative plans in *Whitford v. Gill* (W.D. Wis. 2016) and *Gill v. Whitford*, 585 U.S. 48 (2018) — the U.S. Supreme Court vacated on standing grounds and did not adopt any numerical threshold. The figure appears in neither the EBCA nor any Canadian redistribution jurisprudence. The earlier draft's "historically calibrated to US Congressional delegation sizes in the period 1972–2010" framing was not supported by S-M 2015's actual text — the congressional figure was *seat*-denominated, not percentage-denominated, in the original paper. Three Alberta-calibrated alternatives are documented and defended in `preregistration/thresholds.md` §B.2.1 (Options A–C):

OPTION	THRESHOLD	PROVENANCE	BOTH 2026 ABSOLUTE EGS BELOW?
Reference (US litigation: Jackman in *Whitford*)	7 %	US historical calibration	Yes (+0.04 %, +3.96 % Phase 4C)
A — Assembly-size sensitivity	≈ 2.2 % (2/89 seats)	First-principles scaling, S&M §III.B	**No — minority +3.96 % exceeds threshold** (majority +0.04 % sub-threshold)
B — EBCA statutory-proportional	5 % (one-fifth of ±25 % band)	EBCA § 15(1) proportional anchoring	Yes (+0.04 %, +3.96 % Phase 4C — both below 5 %)
C — Alberta historical-swing	**1.01 % / 4.10 % / 9.71 %** (2019 / 2023 / 2015)	Jurisdiction-normed p95 EG range across Alberta's three measured electoral contexts. 100k-plan ReCom ensembles (seed 3562959107) under 2015 and 2019 vote inputs; 2023 = Option D canonical 1,010,000-plan. Range: floor 1.01 %, centre 4.10 %, ceiling 9.71 %; see Reading paragraph for full table and interpretation.	2019: −1.32 % (p48.3) sub-threshold; 2015: +7.58 % (p30.9) sub-threshold; 2023: +0.10 % (p16.52) sub-threshold **— sub-threshold in all three contexts**

OPTION	THRESHOLD	PROVENANCE	BOTH 2026 ABSOLUTE EGS BELOW?
D — MCMC ensemble 95th percentile	**4.10 %**	1,010,000-plan ReCom canonical ensemble (official EA shapefiles, seed 1432864451, ±25 % accept band with a ±12.5 % proposal step; `data/outputs/simulated_ensemble_percentiles_canonical.csv`): 95th pct EG = +0.0410 as registered; the 2026-07-12 rerun gives +0.0408. (Prior 250k v0_7 DPG run yielded 4.37 %; canonical official-boundary run supersedes it.)	Yes — canonical majority +0.10 %, minority +4.02 % (p94.54), both below 4.10 %

Reading. *Against the EBCA-anchored Option B (5 %), both maps' Phase 4C absolute EGs (+0.04 %, +3.96 %) are sub-threshold and the +3.92 pp inter-map asymmetry is sub-threshold. Against the assembly-size-sensitivity Option A (2.2 %), the majority (+0.04 %) is sub-threshold but the minority (+3.96 %) exceeds the threshold — Phase 4C changed this verdict from the earlier blend reading (majority −0.40 %, minority −1.81 %, both sub-threshold). The 2.2 % threshold marks where EG variation stops being within assembly-size rounding noise, not where a pattern becomes legally or structurally significant. The audit's headline is therefore: the majority map is sub-threshold under all Alberta-calibrated options; the minority map exceeds the assembly-size Option A floor and approaches but does not cross the canonical Option D threshold. The "sub-threshold" characterisation for the majority does not depend on the US-calibrated 7 % figure.* ***Against the Alberta-derived Option D (4.10 % — the 1,010,000-plan canonical ensemble's 95th percentile on official EA shapefiles, superseding the earlier 4.37 % from the 250k v0_7 DPG run), both Phase 4C absolute EGs remain sub-threshold: majority +0.04 %, minority +3.96 % (p94.54). Canonical MCMC-scored values (majority +0.10 %, minority +4.02 %) are consistent to within 0.06 pp.*** *Sign convention: all Phase 4C and canonical MCMC values follow S–M positive-equals-UCP-favoured. Blend-crosswalk values are retired per Phase 4C supersession (§5.2.2). Option C cross-election analysis (2015/2019 vote inputs, area-proportional VA attribution) was run on 2026-05-12 (results below). It establishes the jurisdiction-normed p95 EG threshold range across Alberta's three measured electoral contexts (NDP two-party share 37.3 %–44.0 %). Since EG is intrinsically sensitive to vote-share distribution, the same geographic substrate under different elections produces a different neutral-ensemble 95th percentile. Option C quantifies the range — floor, ceiling, and centre — rather than testing whether 4.10 % is election-invariant. Write-up pre-commitment (2026-05-12, before Option C results arrived): if either the 2015 or 2019 run yields a p95 EG below +0.0402, the outcome will be reported as-is. Option D (4.10 %, 2023 electoral context) remains the primary Alberta-calibrated threshold and Option C results will not be used to retroactively select a threshold changing the verdict on either map. All three p95 values will be reported in full.*

Option C results (completed 2026-05-12, seed 3562959107, 100k plans per context). The full jurisdiction-normed p95 EG range:

ELECTORAL CONTEXT	NDP TWO-PARTY	ENSEMBLE P50 EG	P95 EG	MINORITY EG	MINORITY %ILE	MAJORITY EG	MAJORITY %ILE
2015 (NDP wave)	44.0 %	+8.10 %	**+9.71 %**	+10.54 %	99.45 ⚠	+7.58 %	30.9
2023 (competitive)	42.6 % (election-day)	+1.63 %	**+4.10 %** (registered threshold; rerun p95 +4.08 %)	+4.02 %	94.54	+0.10 %	16.52
2019 (UCP landslide)	37.3 %	−1.25 %	**+1.01 %**	−0.49 %	70.4	−1.32 %	48.3

EG sign convention: positive = UCP-favoured (S–M convention). Real-map EGs recomputed under each year's votes via area-proportional VA attribution on the canonical 4,765-VA substrate. The rows use different ballot universes: the 2015 and 2019 rows spread each election's district totals for all ballots across voting areas by area, while the 2023 row is the canonical ensemble on election-day votes only (the official 2023 all-ballot two-party NDP share is 45.56 %). The 2015 and 2019 ensembles are 100,000 plans in 2 chains with low effective sample sizes (efficiency-gap n_eff 177 and 249; `data/simulation_convergence_diagnostics_threshold_{2015,2019}.json`), below the ~1,000 the audit asks of individual tail claims (§5.2.4), so their p95 thresholds and tail percentiles are low-precision.

What the range shows. The jurisdiction-normed threshold spans 1.01 % to 9.71 % — a nearly 9 pp range across three consecutive Alberta elections. This range is not a weakness of the methodology. It is the central finding of the Option C exercise. EG is intrinsically vote-share-dependent, and Alberta's three measured elections represent three qualitatively different electoral conditions: a UCP landslide (2019, NDP 37.3 %), a competitive return to form (2023, NDP 45.6 % of the two-party vote; 42.6 % on the election-day votes the 2023 ensemble uses), and a historic NDP wave (2015, NDP 44.0 %). The 2023-context threshold (4.10 %, Option D) is the appropriate operative reference for assessing 2026 maps because the 2026 election will be contested under conditions most structurally similar to 2023 — a competitive Alberta election with neither party at a historic extreme.

Minority map: sub-threshold under 2019 and 2023. Over threshold under 2015. Under 2019 votes the minority map scores EG = −0.49 % at p70.4 — entirely within the neutral band. Under 2023 votes it scores +4.02 % at p94.54 — just below the 4.10 % Option D threshold. Under 2015 votes it scores +10.54 % at p99.45, exceeding the 2015-context threshold of 9.71 % (a low-precision tail placement: the 2015 ensemble's efficiency-gap n_eff is 177). Per the pre-commitment (commit 7b68bd9c): this result is reported as-is and does not change the primary verdict. The majority map is sub-threshold under all three contexts.

Why the 2015 threshold is the ceiling, not the operative standard. The 2015 neutral ensemble p50 EG is +8.10 % — meaning the *average randomly drawn neutral Alberta map* under 2015 votes produces an 8 % UCP-favoured EG. This occurs because the 2015 run counts the PC and Wildrose votes together as one UCP-equivalent party. In the real election that vote was split, and the NDP won a large legislative majority on approximately 40.6 % of the popular vote. Merged, the UCP-equivalent holds 56.0 % of the two-party vote and wins about 70 % of the seats: 61 of 87 in the median neutral plan, 63 and 65 of 89 on the majority and minority maps. The NDP's votes in all those lost seats are wasted, so virtually any Alberta map generates a large NDP-waste surplus, and the entire neutral distribution shifts far into positive EG territory. The resulting 9.71 % p95 threshold reflects a once-in-a-generation electoral outcome and is not a plausible calibration reference for 2026 maps.

Comparison with the US 7 % reference. The 7 % figure from the *Whitford* litigation (Stephanopoulos and McGhee's own state-house proposal was 8 %) sits between Alberta's 2023-context threshold (4.10 %) and its 2015-context ceiling (9.71 %), placing it in the middle of the jurisdiction-normed range. This position reveals a structural limitation of importing a US-calibrated figure to Alberta. Under 2023 conditions, 7 % would place a map well above the p95 of 4.10 % — into the extreme tail of the neutral ensemble. The 7 % reference is lenient relative to what Alberta's competitive electoral conditions actually produce. Under 2015 conditions, with a neutral ensemble p50 of 8.10 %, a 7 % EG falls *below* the neutral p50 — the 7 % reference would not flag what any neutral redistricting process would routinely generate under the electoral regime. Under 2019 conditions, 7 % would be approximately seven times the p95 ceiling of 1.01 %, placing it in territory no neutral plan approaches. The 7 % line treats EG magnitude as a property of the map. Alberta's three-election data show the neutral p95 itself varies by a factor of nearly ten across consecutive

elections. The threshold is primarily a function of the electoral regime, not the geography. The 2023-context Option D threshold (4.10 %) is therefore both more conservative and more jurisdiction-appropriate than 7 % for assessing 2026 maps: it is stricter, it is grounded entirely in Alberta's own geographic and legal substrate, and the sub-threshold verdict it produces is harder to achieve than a comparison against the US reference would imply. Under 2023 votes both maps are below both lines; under 2015 votes both exceed 7 %, as most neutral plans do. The Option D result is the stronger claim.

5.2.9 Extended partisan metrics (canonical substrate, refreshed 2026-06-11)

Four additional partisan-bias metrics computed on the canonical Elections Alberta shapefiles + canonical VA centroid-in-polygon attribution + 1,010,000-plan canonical ReCom ensemble (script `analysis/scripts/extended_partisan_metrics_canonical.py`; full numerical detail at `findings/extended_partisan_metrics_canonical.md`). These supplement the four core MCMC metrics with asymmetry measures not requiring an ensemble baseline:

METRIC	2019 ENACTED	MAJORITY 2026	MINORITY 2026
Partisan Bias — turnout-weighted swing (matches ensemble)	**−0.0402**	**−0.0393**	**+0.0169**
Partisan Bias — unweighted swing (historical)	−0.0057	−0.0281	+0.0169
Lopsided Margins t-statistic (Wang 2016)	+3.07 (p=0.003)	**+3.80** (p=0.0003)	+3.17 (p=0.0022)
Proportionality Deviation (sv-curve vs 1:1 line)	+0.0252	+0.0237	**+0.0271**
Responsiveness (slope at 50%)	2.87	**1.12**	1.69

Partisan Bias (T4.9-PB-swing closed 2026-06-12 per T1.7 R1 Ref #6). *Positive PB means the map awards UCP >50 % of seats at a province-wide 50/50 vote. The audit reports* ***two PB values per map*** *because two swing conventions coexist in the literature: the* ***turnout-weighted*** *swing matches the canonical 1.01M ensemble's* `seats_at_50_50 − 0.5` *column exactly (majority −0.0393 = 0.4607 − 0.5; minority +0.0169 = 0.5169 − 0.5; 2019 −0.0402 = 0.45977 − 0.5); the* ***unweighted-mean*** *swing is reported for backward compatibility with the audit's pre-canonical (v0_7) tables. The two are like-for-like comparable only within a single convention. T1.7 R1 Ref #6 flagged the round-1 narrative as confusing the two — the round-1 only reported unweighted-swing PB and then percentile-ranked it against the weighted-swing ensemble, which is not a like-for-like comparison. Round-3 closes this by reporting both columns and using only the weighted column for ensemble percentile placement. The minority's PB = +0.0169 under either convention; both 2019 and majority sit at PB ≈ −0.04 under the turnout-weighted convention. The minority's headline finding, partisan bias favouring the UCP, rests on the four ensemble metrics (§5.2.1–§5.2.7 and §5.4.9), not on PB.*

Lopsided Margins (Wang 2016). All three maps show statistically significant asymmetry ($t > 3$, $p \leq 0.003$): UCP wins by systematically larger margins than NDP wins. This pattern is consistent with natural geographic sorting (UCP voters concentrated in large rural margins by vote geography, not exclusively by drawing) rather than engineered packing, because it persists in the 2019 enacted baseline. The majority 2026 map has the largest t-statistic (3.80); the minority is second (3.17); the 2019 enacted baseline is third (3.07). The lopsided-margins signal is therefore not a distinctive feature of either 2026 proposal — it is a structural property of Alberta's political geography any legal map inherits.

Proportionality Deviation. Measures the area between the seats-votes curve and the 1:1 proportionality line s(v) = v across the full vote-share range. The minority has the largest deviation (0.0271); the 2019 enacted map second (0.0252); the majority third (0.0237). All three are positive (UCP-favoured side of the curve). This is *not* the symmetry-curve Partisan Gini of King 1989 / Gelman & King 1994; the measure answers a different question and the audit does not report it under that name. Earlier drafts of this row reported +0.0079 / +0.0058 / +0.0064 — those values match neither the canonical `findings/extended_partisan_metrics_canonical.json` (0.0237 / 0.0271 / 0.0252) nor any other source the referee could locate; corrected 2026-06-12 per T1.7 R2 Ref #6.

Responsiveness. The 2019 enacted map has the highest responsiveness (2.87 seat-share points per vote-share point, about 2.5 of its 87 seats per point of swing); the minority second (1.69, about 1.5 of 89 seats); the majority third (1.12, about 1.0). Higher responsiveness is often considered a democratic virtue but also implies the lower-responsiveness map will produce fewer seat swings under modest vote-share changes. The two 2026 proposals both reduce responsiveness relative to the 2019 baseline; the majority does so more aggressively. Full output at `findings/extended_partisan_metrics_canonical.json`. The v0_7 DPG substrate predecessor (`findings/extended_partisan_metrics.md`) is now bannered SUBSTRATE-STALE; the canonical numbers above supersede.

5.2.10 Swing-Zone Allocation Test (SZAT) — boundary-choice efficiency decomposition

Why SZAT, given Channel 1 already exists. The ensemble test (Ch1, §5.4.9) asks whether the minority map is extreme relative to neutral Alberta maps. SZAT asks a different question: are *the specific lines on the map* — the boundary choices where the minority drew differently from the majority — partisan-neutral? These are complementary questions, not redundant ones. The ensemble test's potential weakness is the neutral ReCom distribution may not perfectly reproduce every Alberta geographic constraint. SZAT sidesteps this by restricting its analysis to swing-zone Voting Areas (those assigned differently between the two proposals), effectively differencing out everything the two maps share — including Alberta's underlying political geography, the EBCA constraint set, and the population substrate. What remains after the differencing is a signal about boundary-placement choices alone.

What SZAT measures. The partisan-bias metrics in §5.2.1–5.2.9 ask whether a map as a whole is an outlier. SZAT asks a finer question: of the 2,110 Voting Areas assigned to *different* Electoral Divisions under the minority map versus the majority map (swing zones), do the minority's boundary choices systematically shift partisan vote efficiency in one direction?

Method. Each VA centroid is spatially joined to both canonical boundary files (Elections Alberta official shapefiles; `data/shapefiles/canonical/`). The efficiency gap is computed under each map's spatial assignment using 2023 election-day VA vote totals (`va_polygons_with_full_2023_votes.gpkg` columns `va_ndp`/`va_ucp`; two-party total

~896,644; NDP two-party share 42.60%). SZAT score = EG(minority) − EG(majority), decomposed over the swing zones only. A 10,000-permutation bootstrap tests whether the minority's specific allocation of swing-zone VAs is partisan-neutral. Seed `get_canonical_seed("szat-bootstrap")` anchored to drand round 5,500,000 (pre-committed at `d2aea42`). Full methodology: `analysis/methodology/szat_methodology.md`. Script: `analysis/scripts/szat.py`.

EG sign convention (this subsection only): positive = more NDP votes wasted than UCP. SZAT uses canonical EA geometry and 2023 election-day VA vote totals (same substrate as the MCMC ensemble), so its EGs equal the canonical values (+0.10 %, +4.02 %); the Phase 4C values in §5.2.1 (+0.04 %, +3.96 %) agree to within 0.06 pp.

Results.

	VALUE
EG majority (canonical EA geometry, election-day votes)	+0.000982
EG minority (canonical EA geometry, election-day votes)	+0.040194
SZAT score (minority − majority)	**+0.039211**
Bootstrap p-value (two-tailed, 10,000 permutations)	**0.0024**
Bootstrap null 97.5th-percentile (upper bound)	**+0.036652**
Observed score vs null upper bound	observed +0.039211 exceeds null 97.5th by 7%

The minority map's specific boundary choices — the swing-zone allocations — produce a 3.9 percentage-point increase in NDP vote waste relative to the majority map. The null distribution's 97.5th-percentile upper bound is +0.037. The observed +0.039 exceeds it (p=0.0024 two-tailed, standard i.i.d.-flip permutation). ***Block-permutation null (added 2026-06-13).*** *Under a block-permutation null that corrects for spatial autocorrelation across adjacent Voting Areas — the 2,110 swing-zone VAs cluster into a single connected component of 2,086 VAs, which violates the independence assumption of the standard test — the bootstrap returns p≈0.19, not significant. SZAT is therefore retired as a confirmatory channel; the standard-permutation result (p=0.0024) is preserved here for audit reproducibility and exploratory reference.*

Artifact provenance and estimator note (2026-07-08). The committed source artifact `findings/szat_summary.json` was overwritten on 2026-06-13 by a T1.10b block-permutation smoke test (n = 100, p = 0.0198; commit `cc1b290`) and remained in that state until 2026-07-08, when it was restored and verified by a full re-run of the reported configuration (drand seed 23,687,475, i.i.d. null, 10,000 permutations). The re-run reproduced exactly 24/10,000 exceedances, the identical SZAT score (+0.039211), and the identical null CI. The reported p = 0.0024 is the raw exceedance ratio 24/10,000 (it postdates the registration: OSF 6pt83 reports p = 0.0044, from the first run, which placed each VA by its true centroid; see the post-registration note below); the regenerated artifact reports the same run as p = 0.0025 under the (b+1)/(B+1) estimator adopted per T1.10 (the file records `bootstrap_b_extreme: 24`). Both conventions describe the same permutation result. `szat.py` now writes any non-registered configuration to `*_exploratory` output paths so exploratory runs can no longer overwrite the registered artifact.

Regional decomposition (swing zones only):

REGION	SZAT CONTRIBUTION
Rest of Alberta	+0.01499
Edmonton	+0.00838
Mountain-West	+0.00573
Calgary	−0.00787
Canmore / RMH focal EDs (Canmore-Banff, Canmore-Kananaskis, RMH-Banff Park)	+0.00609

The dominant contributor is Rest of Alberta (+0.015), with Edmonton second (+0.008). Calgary swing zones run in the opposite direction (−0.008), partially offsetting. The four regional terms sum to +0.021, about 54 % of the +0.039 total; the rest is not attributed by region. The Canmore/RMH boundary choices motivating this test contribute +0.006 — meaningful, but not the primary driver of the overall score.

Interpretation. The minority map's boundary choices, in aggregate, reallocate swing-zone voters in a way that increases NDP vote waste. The effect is distributed across the province rather than concentrated in one region. SZAT does not replace the MCMC ensemble (which tests the whole map against neutral draws) but supplements it as exploratory context: the ensemble tests whether the map is anomalous. Under standard permutation, SZAT's regional decomposition identifies which specific boundary decisions are most associated with the between-map difference. However, the block-permutation null (p≈0.19) means the overall SZAT result does not reach confirmatory significance. The headline rests on the simulation (Ch1) alone.

Registration disclosure. The SZAT bootstrap null was registered at AsPredicted #289,469 and OSF 6pt83 (filed 2026-05-06 at 21:25 MDT) after its first results were known. The seed's salt is cited at `d2aea42` (2026-05-06, 15:44 MDT; a commit the 2026-05-12 history rewrite orphaned). No record dates the salt to 2026-04-27: the copy of `drand_seed.py` uploaded to OSF that day holds no salts (Amendment 5, Part 30). The specific numerical results were known to the analyst at the time of filing — this diverges from the ideal prospective sequence and is disclosed here and in the registration record. SZAT is retired under the block null; its results are exploratory.

Post-registration change of point method (2026-05-08; rerun 2026-05-10). The first SZAT run (p=0.0044, 2,108 swing zones; commit `01844f66`) placed each VA by its true centroid. Commit `d8fa62c2` (2026-05-08) changed `szat.py` to `representative_point()`, the point the MCMC scoring uses, which always falls inside the VA polygon; the rerun of 2026-05-10 (commit `7bc98a85`) found 2,110 swing zones, tightening the bootstrap p from 0.0044 to 0.0024. The code change is the cause, not the VA file. Both runs read `va_polygons_with_full_2023_votes.gpkg`, a superset file carrying the same election-day vote columns (`va_ndp/va_ucp`) alongside additional advance-vote columns (`va_ucp_full/va_ndp_full`), and the committed `va_polygons_with_2023_votes.gpkg` has identical geometry: on either committed file the true centroid gives 2,108 swing zones and `representative_point()` gives 2,110. The SZAT reads only the election-day columns, so the vote substrate is election-day throughout both runs. The OSF registration (6pt83), which reports p = 0.0044, pre-dates the change, so the reported 0.0024 is a post-registration

value. *Note:* an earlier version of this paragraph incorrectly described this update as a substrate change to "full advance-vote" with NDP two-party share rising 42.60% → 44.66%; the description was false. The earlier paragraph is documented in DOCUMENTED CORRECTIONS below.

Apportioned-ballot sensitivity (unregistered, 2026-05-12). Running the SZAT on election-day plus apportioned advance/mobile/special ballots (`va_ucp_full/va_ndp_full`; 1.54M of 1.71M two-party votes; Vote Anywhere excluded; UCP 55.3%) yields SZAT score +0.053, EG majority +0.0052, EG minority +0.0579, bootstrap p < 0.0001 (0 of 10,000 permutations met or exceeded the observed score; null 97.5th = +0.038). The signal strengthens substantially on this substrate. Regional decomposition shifts materially: Calgary swing zones reverse from a slight offset (election-day: −0.008) to the strongest contributor (+0.018), suggesting advance-ballot voters in the Calgary boundary-choice zones skew more NDP than election-day-only voters. This sensitivity is unregistered; the election-day result (p=0.0024, registered after first results and retired under the block null) remains the reference result. Output: `findings/szat_summary_full_votes.json`. **[2026-11-05 — superseded in part; see C51.]** The Vote Anywhere exclusion this substrate carries was not needed: Elections Alberta reports those ballots under the voter's own district. On the all-ballots substrate (`va_polygons_with_all_2023_ballots.gpkg`, which equals the official result in all 87 districts) the SZAT score is +0.0525 (EG majority −0.0270, minority +0.0255), i.i.d. permutation p = 0.0005 (4 of 10,000). The score is essentially unchanged; both maps' EG levels fall. Output: `findings/szat_summary_all_ballots.json`.

5.2.11 Inter-map comparison permutation test (Ch1-COMP)

Pre-registered at OSF:yvc7g (drand seed 1823538405, salt "ch1-comp"). H₀: the minority-majority partisan-metric gap is no larger than the one for randomly drawn neutral-plan pairs. Results are reported regardless of direction per pre-commitment. The test runs in two versions: an EG-only one-tailed version and a Mahalanobis joint one-tailed version. Results and contextual framing in §5.4.9.

5.3 Signature detection

5.3.1 Packing signature test

Formal packing signature detection applies the P1–P3 criteria (district size above mean, winning margin at least 15 pp above the provincial mean, counterfactual seat loss verifiable). A signature is detected only if all three hold.

Pre-registration disclosure. The P/C/E criteria and their numeric thresholds were specified in the same analytical-pass commit (`249cff7d`, 2026-04-22 10:56:11 −06:00) as the detection run. `git diff 5b0bc06 249cff7d -- v1_2_gerrymander_audit_prompt.md` shows the criteria were added in that commit, not before it. The honest framing is: the criteria were

specified at the head of the analytical session producing the detection, and the detection was not run against criteria observed from the data — but the separation is intra-session (minutes, not hours), and the framework is therefore not independently time-stamped. The criteria were applied symmetrically to both 2026 maps; where the majority failed a criterion, the failure is reported with the specific numeric value rather than omitted. The advisory panel's 91-seat map is the held-out test closing this residual. Its tests are in `preregistration/november_2026_scoring_spec.md` (June 2026, dated in this repository), and the 17-test signature-detection checklist on OSF 9wp5y (2026-05-07) was scored on the panel's map on 2026-11-09, after its 72-hour window (`findings/checklist_9wp5y_panel_map.md`); qsgy8 holds four tripwires, not this framework (§5.5). The current detection run is exploratory: the criteria were written in the same commit as their first run.

OSF file content disclosure (verified 2026-05-09). The four OSF registrations (w2s8k, r3zm7, qsgy8, 6pt83) each contain two files: `dpg2_experiment_plan.md` (DPG v11 error decomposition, hypotheses H1–H5, test suite T-A–T-D) and `drain_v2_plan.md` (§5.3.5 drain test improvement plan). Neither file names or specifies the Mahalanobis joint tail (Ch1) or SZAT bootstrap (Ch2) methodology. The registration forms are another matter: 6pt83's form registers the SZAT bootstrap, after its first results were known (Amendment 5, Part 30; §5.2.10). Ch1 has no corresponding named OSF pre-registration document. This is a separate dimension of the provenance disclosure: the Fisher combination of Ch1 and Ch2 (§5.4.9, $p = 4.61 \times 10^{-8}$) should not be described as pre-registered in the sense its input channels are specified in the OSF files, even though both input statistics' seeds derive from a public drand round (Ch1's salt fixed in code before the shapefiles arrived, Ch2's about six hours after; Amendment 5, Part 30; dated by the git record). Registration 6pt83 was timestamped approximately 3 hours after the shapefile commit (2026-05-07 03:25 UTC vs commit 2026-05-07 00:12 UTC) and cannot be treated as pre-dating the data. W2s8k, r3zm7 and qsgy8 were registered at 21:50 UTC on 2026-05-06, about six hours after the shapefiles arrived (09:51 MDT, 15:51 UTC), and also post-date the data.

Threshold provenance. P1 at +5% of provincial mean is one-fifth of the Act's ±25% statutory band (conservative). C3 at ±25% is the Act band directly. P2 at +15 pp above mean winning margin yields an operational "safe-seat" cut-off of about 40–43 pp on the vote files scored here (provincial mean margins 24.9–27.6 pp), above the 20 pp threshold used in Chen (2017). E1–E3 are conjunctive (all three must hold), the stricter test. These thresholds were written in the same commit as the detection run (see above), so the test was always exploratory; they are applied identically to both 2026 maps.

Packing signature in Calgary Zone A under the minority 2026 map. Not detected (rescored 2026-11-01 on the official vote attribution: `analysis/scripts/packing_signature_rescore.py`, `data/outputs/packing_signature_rescore_2026-11-01.json`; earlier versions recorded "Detected" with P2 as a pass; DOCUMENTED CORRECTIONS C50). The signature needs P1, P2 and P3 all to hold, and P2 fails.

- **P1 (size above mean):** Zone A mean population 61,225 vs provincial mean 54,929 = +11.5%. Threshold is +5%. **Pass.** On the majority map Zone A districts average 2.8% above the provincial mean. This is a population-equality finding (§5.1.2), not by itself a packing signature.
- **P2 (winning margin above mean):** On the canonical Phase 4C attribution (`data/outputs/phase4c_per_ed_votes_minority.csv`; 2023 election-day votes, two-party margin), 8 of the 17 Zone A districts are NDP-won. Their mean winning margin is 15.0 pp, against a provincial mean of 27.6 pp: 12.6 pp **below** the provincial mean, where P2 needs 15 pp above it. The file this bullet used to cite (`data/outputs/votes_2023_minority.csv`) gives 9 of 17 NDP-won, 12.3 pp below. The "13 of the 17" it reported was the majority map's count in that file. **Fail.**
- **P3 (counterfactual seat loss):** Not reached, because P2 fails. (Earlier versions scored a pass, reading the 12.2% zone gap as "roughly 113,000 NDP-leaning voters" needing 1–2 more seats; 113,000 is the zone's extra residents, 17 × 6,656, not voters.)

No packing signature detected in Calgary under the majority 2026 map. P1 fails: Zone A's mean of 56,460 is 2.8% above the provincial mean, below the +5% threshold (and 0.4% above Zone B's 56,255). P2 fails as well: 9 of 17 Zone A districts are NDP-won, with a mean margin 12.1 pp below the provincial mean.

The 2019 baseline was not tested. P1–P3 evaluation against the 2019 map would require running the full test and is outside this audit's current scope (the 2019 map is not the primary comparator).

5.3.2 Cracking signature test

Formal cracking signature detection applies the C1–C3 criteria (community split across more districts than centre-of-gravity assignment would produce, community a minority in each resulting district, community large enough for a single district).

Cracking signature for Airdrie under the minority 2026 map. Not detected (rescored 2026-10-31 on the official boundaries, `data/outputs/cracking_signature_rescore_2026-10-31.json`; earlier versions recorded "Detected" with C2 as a pass; DOCUMENTED CORRECTIONS C46). The rule needs all three criteria, and C2 fails. Its "forced by population" outcome needs C1 and C2 both met, so it does not apply either.

- **C1 (split count exceeds necessity):** Airdrie (population 74,100 at 2021 Census; 85,805 at the 2024 municipal census, census day April 1, 2024 [City of Airdrie, 2024; the provincial Municipal Affairs population list records 85,505]; 90,044 at the April 2025 municipal census) is split across 4 districts in the minority map, three of which hold at least 2 % of its residents (the audit's piece rule; Olds-Three Hills-Didsbury takes about 350 people); one of the four (Airdrie-East) is named for Airdrie, and two others carry it in compound Calgary names. Under the majority map, Airdrie is split across 2 districts, both named

Airdrie. The majority's 2-district split is the centre-of-gravity minimum for a city of this size at any of the cited vintages. 4 districts (3 by the piece rule) is above necessity. **Pass.**

- **C2 (community is minority in each district):** Not in every district. On 2021 census areas over the official boundaries (`data/outputs/airdrie_split_shares_2026-10-31.json`), Airdrie residents are 89.6 % of Airdrie-East (40,501 of 45,218), which holds 54.7 % of the city. They are a minority in the other three: Calgary-Airdrie 43.8 %, Calgary-Foothills-Airdrie West 34.1 %, Olds-Three Hills-Didsbury 0.8 %. The criterion must hold in each district, and it fails in Airdrie-East. **Fail.**
- **C3 (single-district feasibility, restated 2026-06-12 per T1.7 R2 Ref #11):** the ±25% statutory upper bound is 68,661 (54,929 × 1.25). Airdrie's three census vintages all exceed this ceiling: 2021 = 74,100 (+7.9% over the bound); 2024 = 85,805 (+25.0% over the bound — 24.97% precisely); 2025 = 90,044 (+31.1% over). **Single-district draw is infeasible at every cited vintage.** Two-district draw is at the 2024 minimum (each half ≈ 42,902 — within the ±25% band where the lower bound is 41,197); an even 4-way split at the 2025 vintage (each quarter ≈ 22,511) would fall below the 41,197 lower bound, so a 4-way split cannot be a multi-district allocation balanced within the band — pieces of that size must be joined to territory outside the city. The minority's actual pieces are uneven (54.7 %, 24.0 %, 20.9 % and 0.5 % of the city; see C2). Earlier drafts of this criterion ("single-district feasible at 2021 census, three-district-permissible at 2025+") contained arithmetic errors at both ends; the corrected reading is: minimum 2 districts at all vintages; the minority's 4-way split is two divisions above the minimum (one above it by the piece rule). C1 one bullet up correctly identifies the majority's 2-district split as the centre-of-gravity minimum at any vintage. **As registered — one district within ±25 % (`preregistration/thresholds.md` row 12) — C3 is not met at any cited vintage: Airdrie is too large for one district. The 2026-06-12 restatement, in line with the gloss in `thresholds.md` B.3.3, reads C3 as a two-district test and scores a pass at the 2-district minimum (all vintages). The result above is the same under either reading, because C2 fails.**

No cracking signature detected for Airdrie under the majority 2026 map. The majority's 2-district split matches centre-of-gravity minimum; C1 fails, and so does C2 (Airdrie residents are 97.5 % of Airdrie-West and 75.8 % of Airdrie-East). **Federal context.** Under the 2023 Representation Order, drawn by the Federal Electoral Boundaries Commission for Alberta (chaired by Justice J.D. Bruce McDonald, with members Donald Barry and Donna Wilson), Airdrie sits within one federal riding, Airdrie—Cochrane. The federal quota (about 115,000) is about twice the provincial one, so a city of Airdrie's size needs at least two provincial districts. This is context, not a benchmark.

Cracking signature check for Cochrane under the minority 2026 map: Not detected (rescored 2026-10-31 on the official boundaries; earlier versions reported a cracking-adjacent pattern with C1 and C2 passing; DOCUMENTED CORRECTIONS C46). C1 fails: Cochrane is not divided. Calgary-Nolan Hill-Cochrane holds 99.9 % of its 2021 residents (32,169 of 32,199), and no other district holds 2 %; pairing Cochrane with a Calgary neighbourhood instead of

its rural neighbours is a choice of partner, not a split. C2 fails: Cochrane residents are 65.9 % of Calgary-Nolan Hill-Cochrane, outnumbering its Calgary (8,639) and Rocky View County (7,999) residents, and would still be a majority if all of the district's growth to its official total fell outside the town. C3 fails — Cochrane at 34,000 is below the provincial average and would normally be bundled with surrounding rural communities (which the majority does as Cochrane-Springbank); the "could have been one district alone" test fails at 34,000 people. None of the three criteria holds. The community-of-interest question about the Calgary pairing remains; this test does not measure it.

No cracking signature detected under the majority 2026 map for any of Cochrane, Chestermere, or Airdrie (each handled within centre-of-gravity minimum).

5.3.3 Engineered-boundary signature test

Formal engineered-boundary detection applies the E1–E3 criteria (boundary through negligible-population territory, no qualification without the extension, no stated community-of-interest rationale).

Engineered-boundary signature at Rocky Mountain House-Banff Park under the minority 2026 map. Not detected. The original E2 (Reading A) is a statutory-eligibility test ("without extension, ED would not qualify"), and the §15(2) re-audit against corrected thresholds finds the district qualifies without the extension, so E2 fails. A reformulated E2 (Reading B, exploratory), which T1.7 Refs #7 and #11 both flagged as outcome-dependent criterion switching, asked whether the minority chose uninhabited territory over populated community-of-interest alternatives. Its premise was false: the minority's district already contains every alternative this section named — nearly all of Clearwater County (including Caroline and Nordegg), the western portion of Mountain View County with the Town of Sundre, and the Municipal District of Bighorn (final report p. 352; minority report p. 66). Reading B is withdrawn (DOCUMENTED CORRECTIONS C50). The headline signature count is **zero**: no formal signature is detected on the official maps (packing fails its margin test, §5.3.1; cracking is not detected, §5.3.2; the engineered-boundary signature is not detected). See `analysis/methodology/population_deviation_reaudit.md` for the eligibility re-audit and `analysis/methodology/reference/minority_rationales_validation.md` for the alternative-configuration analysis.

- **E1 (boundary through negligible-population territory):** The district's southwest extension traces through Banff National Park land to reach the British Columbia border. An area-weighted 2021-Census DA pull (`analysis/methodology/reference/banff_extension_population_check.md`) over a longitude/latitude slice approximating the extension (west of −115.5°, north of 51.4°, on the traced v0.8 polygon) gives about 491 residents, almost all from two large rural DAs whose residents mostly live outside the park; the source estimates the park-land population at likely fewer than 50, and the Lake Louise townsite is outside the district. Either figure is far below any normal ED's population base. Confirmed on the published

minority Alberta overview map (Appendix E, p. 73). **Pass** (negligible population: likely under 50 on the park land; ~491 is an area-weighted upper proxy for the slice).

- **E2 (original, Reading A — no qualification without the extension):** Under the corrected §15(2) thresholds (see §5.1.4 re-audit), the ED qualifies on 3 or 4 of 5 criteria (depending on criterion (b)) on the 2019-predecessor-plus-Clearwater-County footprint alone, without the park extension. **Fail.** (Reading B said the minority could instead have extended into Caroline, Nordegg, more of Mountain View County, Bighorn MD or a restored Sundre connection. The district already contains all of them, so that reading is withdrawn.)
- **E3 (no stated community-of-interest rationale for the extension):** Commission p. 352 cites "the historical precedent of portions of Banff National Park being included in a west central Alberta electoral division." History is a proper consideration in drawing boundaries (the commission, citing *Carter*, final report p. 35; see §2), but it is not itself a community-of-interest rationale. The extension adds few residents (likely fewer than 50 on the park land, per `banff_extension_population_check.md`; its area-weighted slice gives ~491, mostly people living outside the park) — not a community-of-interest base. **Pass under the substantive C-of-I test, qualified under a mechanical stated-rationale test.**

E2 fails, so the signature is **not detected**. The two E2 framings are recorded below as history; only Reading A stands:

E2 — Reading A (original eligibility-only framing): E2 as initially specified asked: *"Would the district lose its §15(2) qualification if the NP extension were removed?"* Under corrected §15(2) thresholds documented in §5.1.4, RMH-Banff Park satisfies 3 or 4 of 5 qualifying criteria (depending on criterion (b)) on the 2019-predecessor-plus-Clearwater-County footprint without the park extension. Answer: the ED qualifies without the extension. Under Reading A, **E2 does not pass**. The signature is not detected.

E2 — Reading B (substantive choice-over-alternatives framing; withdrawn): E2 reformulated asked: *"Did the minority choose uninhabited territory when inhabited community-of-interest alternatives were available?"* Earlier versions answered yes, naming Caroline, Nordegg, Mountain View County, Bighorn MD and the Sundre area as populated options passed over. The minority's district contains all of them (final report p. 352), so the premise fails and Reading B is withdrawn. The park extension still adds few residents (likely fewer than 50 on the park land) and no community of interest; that is a description, not a signature.

The rest of the audit's findings do not depend on this signature. The MCMC ensemble (Mahalanobis $p = 8.80 \times 10^{-7}$, a parametric extrapolation; the sample alone supports p below about 6.9×10^{-4}) carries the partisan evidence, and the four remaining geometry-independent structural dimensions describe how the two maps differ. See `analysis/methodology/population_deviation_reaudit.md` for the eligibility re-audit and `analysis/methodology/reference/minority_rationales_validation.md` for the alternative-configuration analysis.

The case once made for Reading B (withdrawn with it). Canadian statutory interpretation follows Driedger's purposive principle as codified by the Supreme Court in *Rizzo & Rizzo Shoes Ltd. (Re)*, [1998] 1 S.C.R. 27: "*the words of an Act are to be read in their entire context and in their grammatical and ordinary sense harmoniously with the scheme of the Act, the object of the Act, and the intention of Parliament.*" The object of §15(2) is to preserve representation for genuinely remote communities whose residents would otherwise be ill-served by standard ±25% population districts — it is not a license to engineer a criterion-count via uninhabited territory. The minority's configuration satisfies the *letter* of §15(2) (four or five criteria met) but the park extension adds no represented community and serves no community of interest. A boundary meeting the letter of an exception while defeating its purpose is what the engineered-boundary signature was designed to flag; the purposive argument does not rescue Reading B, whose factual premise failed.

No engineered-boundary signature detected under the majority 2026 map. The majority's §15(2) invocations (Central Peace-Notley, Lesser Slave Lake, Canmore-Banff — the last now passing at 3/5 under corrected thresholds) do not show boundary extensions through negligible-population territory in the available imagery.

5.3.4 Signatures summary

SIGNATURE TYPE	MINORITY 2026	MAJORITY 2026	2019 BASELINE
Packing (Calgary Zone A)	Not detected (P2 fails: 8 of 17 Zone A districts NDP-won, mean margin 12.6 pp below the provincial mean; P1 passes)	Not detected (P1 and P2 fail)	Not tested
Cracking (Airdrie)	Not detected (C2 fails: Airdrie-East is 89.6 % Airdrie)	Not detected	Not tested (2019 split Airdrie between Airdrie-Cochrane and Airdrie-East)
Cracking-adjacent (Cochrane merged with Calgary)	Not detected (C1, C2 and C3 fail)	Not detected	Not applicable
Engineered boundary (RMH-Banff Park NP extension)	Not detected (E2 fails under the original Reading A; Reading B withdrawn — see §5.3.3)	Not detected	Not applicable

No formal signature is detected on the official maps (packing fails its margin test; cracking and the engineered-boundary signature are not detected). Rescored on the official vote attribution, the packing signature's P2 fails (§5.3.1); rescored on the official boundaries, the Airdrie cracking signature and the Cochrane borderline pattern are not detected (§5.3.2). The engineered-boundary test fails under its original E2: under corrected §15(2) thresholds (see §5.1.4), RMH-Banff Park qualifies on 3 or 4 of 5 criteria without the park extension. A mid-audit reformulation of E2 ("what alternatives were available and which was chosen") rested on populated territory the minority supposedly passed over (Caroline, Nordegg, Mountain View County, Bighorn MD, Sundre area); the district contains all of it, so the reformulation is withdrawn. What remains is description: the minority's Calgary Zone A districts average 11.5% above the provincial mean (a population-equality finding, §5.1.2), Airdrie is divided four ways by territory, and the park extension adds no represented community. All of these tests were written in the same commit as their first run and are exploratory.

5.3.5 Packing-cracking coupling via neighbour-drain adjacency (new, 2026-04-24; honest retrospective)

Tests §5.3.1 (packing) and §5.3.2 (cracking) measure those phenomena as separable whole-map statistics. They do not ask whether the two are spatially *coupled* — whether a packed ED tends to sit next door to a cracked one, as would be expected under a partisan-drain design pattern. We operationalise coupling via a neighbour-drain adjacency test (script `analysis/scripts/neighbour_drain_adjacency.py`; full methodology at `findings/neighbour_drain_analysis.md`). For each directed pair (X, Y) of EDs sharing a common polygon boundary, we flag a **chain signal** when X's winning-party surplus $s_X \geq 0.15$ AND Y's winning margin $m_Y \leq 0.05$. A **coupled chain signal** additionally requires the winning party in X to equal the losing party in Y (the target party the map is allegedly draining). The test was **pre-committed** in `preregistration/null_hypotheses.md` §2.1 before execution.

Result (v0_2 provisional DPG geometry & 2023 vote substrate; superseded). The canonical run on the official shapefiles gives minority 1 coupled chain signal, majority 2 and 2019 enacted 5 (ratio 0.50×; `findings/neighbour_drain_analysis.md`); r3zm7, run the same day on official geometry with a buffer fallback, reported majority 3 and minority 0. The v0_2 table is kept as the record the paragraphs below were written against:

MAP	COUPLED CHAIN SIGNALS	UNCOUPLED CHAIN SIGNALS
2019 enacted	5	3
Majority 2026	6	2
Minority 2026	**2**	4

The minority map produces the fewest spatially-adjacent coupled pairs *on every substrate except v0_8 (below). The minority's v0_2 coupled count is 2, which is 0.33× the majority's. This finding initially appears to exonerate the minority map from a "pack-and-drain" adjacency gerrymander. However, this test assumes gerrymanders rely on maintaining district boundaries between an 80-20 packed district and a 49-51 cracked district (the "bacon strip" model).*

Hybridization reading (dropped; see "The honest reading" below). An earlier draft argued that the minority's partisan differences come not from placing packed districts next to cracked ones but from **hybridization** (city-splitting): dividing cities (like Airdrie and Red Deer) and pairing the pieces with surrounding territory, which would hide any packing and cracking inside the hybrid districts where an adjacency test cannot see it. The test cannot show that, and the premises have since gone: no packing or cracking signature is detected on the official maps (§5.3.4), and Airdrie's pieces go mainly to Calgary hybrids, not to rural districts (three pieces by the 2 % rule; §5.3.2). The "pack-and-hybridize versus pack-and-drain" label is not used.

Threshold sensitivity (responding to the pre-committed threshold-arbitrariness criterion: §2.1 criterion 2, ratio stability, in `preregistration/null_hypotheses.md`): the magnitude of the inter-map difference is threshold-dependent (counts at the end of this paragraph). But the **direction** of the difference (minority ≤ majority ≤ 2019) is stable across all three thresholds. The phase-space density plots (`data/maps/neighbour_drain_phase_space_{2019,majority,minority}.svg`; regenerated 2026-07-13 — the prior `.png` citation pointed at figures dated 2026-04-24, predating the canonical shapefile switch) are drawn from the official-map data, which give

the same ordering but not an empty quadrant for the minority: it has 2, 1 and 0 coupled signals at the three thresholds, against the majority's 9, 2 and 2 and 2019's 11, 5 and 5 (`data/neighbour_drain_summary.json`).

Integration with the three-axis robustness framework (`preregistration/null_hypotheses.md` §7): an earlier draft classed the "pack-and-divide vs pack-and-drain" distinction as **[SRD]** and placed it in the strongest-defensible-finding set beside population equality, anchoring and the tiered majority-claim refutation. The distinction is dropped (above and below), and anchoring has been retired (§5.8.5), so the classification no longer applies.

v0_8 full-coverage re-run (2026-04-25; cross-substrate disagreement, reported transparently). The neighbour-drain test was re-run against the v0_8 full-coverage geometry (89/89 EDs both maps via 2019-Tier-A inheritance fill; `archive/provisional_geometries/dpg/logs/v0_1_neighbour_drain_v8_full.log`). The directional result *changes*:

MAP	ADJACENT PAIRS	TOTAL SIGNALS	COUPLED	UNCOUPLED	RATE
2019 enacted	486	8	3	5	1.65 %
Majority 2026 (v0_8 full)	582	8	3	5	1.37 %
Minority 2026 (v0_8 full)	460	**14**	**4**	10	**3.04 %**

*Under v0_8 full coverage, the minority's overall chain-signal rate is **2.22× the majority's** and **1.84× the 2019 baseline** — the opposite directional result from the v0_2 partial-coverage reading above. The coupled-count ratio (minority 4 / majority 3 = 1.33×) is still under the pre-committed 1.5× pass threshold, so the pre-registered pass criterion technically holds, but the overall rate signal is in the opposite direction from the partial-coverage finding.*

What changed. The v0_2 substrate used the audit's earlier polygon set, which under-counted central-Calgary urban adjacencies (sub-kilometre topology gaps) and over-counted minority isolates via K-nearest fallback. The v0_8 full-coverage substrate has consistent topology (Phase 4 1m precision pass; v0_8.2 inheritance fill closes the urban-empty-ED gap driving the K-nearest fallback). Under the cleaner topology, the minority's *uncoupled* chain signals (party-A packed in X, party-B cracked in Y) jump from 4 to 10 — these were previously masked because the under-counted urban Calgary adjacencies hid the Calgary-South / Calgary-Currie / Chestermere-Strathmore chain pairs the v0_8 substrate now resolves.

The honest reading. The pre-committed pass criterion (coupled count ratio ≤ 1.5×) was met under both substrates. But the v0_2 substrate's "minority is *less* adjacency-coupled" finding does not survive the cleaner topology — the minority is *more* chain-signal-prone than majority or 2019 on the v0_8 substrate, both in coupled count and especially in overall rate. The audit reports both readings and drops the strong "pack-and-divide vs pack-and-drain" archetype claim above (which depended on the minority's low coupled count). On the v0_8 substrate the minority's chain-signal rate is the highest of the three maps; with no packing or cracking signature detected on the official maps (§5.3.4), there is no signature finding for

it to corroborate or invert. The cross-substrate disagreement is itself a documented finding per the multi-method-reporting discipline.

Justify-or-drop validation (2026-06-11, `findings/drain_metric_validation.md`). A three-pronged validation was run against the Channel 3 metric:

- **V1 — synthetic ground truth (PASS).** A constructed 3×3 ED grid with a known pack-and-crack pattern (P4 packed 90/10 against NDP, eight outer EDs cracked 48/52 against NDP) produces `drain_score = 0.00996` against a neutral 50/50 jittered grid's `drain_score = 0.0`. The metric detects a constructed pack-and-crack signature, satisfying construct validity.
- **V2 — bivariate Local Moran's I numerical anchor (FAIL).** The audit's framing of Channel 3 as a "directional bivariate Local Spatial Autocorrelation / LISA analog" was checked numerically: for every directed adjacent pair compute `I_pair = z_s(X) × (−z_m(Y))` and correlate with drain-intensity at the same pair. Pearson r = 0.114 (majority) and −0.002 (minority), well below the pre-committed 0.30 anchor threshold. **The LISA framing is rhetorical, not numerical, and is not used.** Channel 3 is a bespoke pack-and-crack adjacency statistic without external statistical heritage.
- **V3 — pre-registered Prediction A on canonical substrate (PASS).** Recomputing the continuous drain_score on the canonical Elections Alberta shapefiles + canonical VA centroid-in-polygon attribution (the substrate every other audit channel uses) gives `majority = 0.00721`, `minority = 0.00059`. Pre-registered Prediction A (drain(majority) > drain(minority)) confirms. The label-shuffle null on the same canonical substrate gives P(majority > minority | random labels) ≈ 0.91, so the direction is the geometry-favored one and is not strong evidence on its own.
- **Substrate-stale numbers replaced; canonical Phase B null now landed (2026-06-11, `findings/drain_label_shuffle_null_canonical.md`).** The original Phase B numbers (`findings/drain_label_shuffle_null.md`: majority drain = 0.000179, minority = 0.006176; majority z = −2.915 "anomalously low") were computed against a DPG-era / blended-vote substrate and have been bannered SUBSTRATE-STALE. The canonical-substrate Phase B re-run (10,000 label-shuffle permutations on official Elections Alberta shapefiles + canonical VA centroid-in-polygon attribution) reports:

MAP	OBSERVED DRAIN_SCORE	NULL MEAN	Z	PERCENTILE	P (TWO-TAILED)
2019 enacted	0.001530	0.052987	−3.520	0.0 %	0.0000
Majority 2026	0.007213	0.049257	−3.173	0.0 %	0.0002
Minority 2026	0.000591	0.028057	−2.750	0.0 %	0.0002

Three substantive readings emerge from the canonical re-run: (i) Pre-registered Prediction A (drain(majority) > drain(minority)) is CONFIRMED on canonical substrate, reversing the stale-substrate failure. (ii) All three maps are anomalously low against their own label-shuffle null — the 2019 enacted map is the most anomalously low (z = −3.52), the majority second (−3.17), the minority third (−2.75); the metric does not discriminate the 2026 commission maps from the 2019 baseline at the directional level. This means r3zm7's Prediction B (both maps inside the null, p > 0.05) failed. (iii) The original framing of the majority as singularly "anomalously clean" was a substrate artefact: on canonical substrate every Alberta map is anomalously clean by this null. Channel 3 remains excluded from the Bonferroni headline combination (p ≈ 1.76×10 ⁻⁶, whose Ch1 input is a model extrapolation; the sample alone supports Ch1 p below about 6.9×10 ⁻⁴), so this finding does not change the audit's headline.

5.4 MCMC constraint-bound ensemble

Terminology note (2026-04-24, per `preregistration/retraction_conditions.md` §9 item 1). The language of "ensemble median," "neutral map," and "geometric baseline" is replaced throughout this section — and in §5.2.5 — with "**constraint-bound expectation.**" The ReCom ensemble samples from the universe of compact, contiguous maps satisfying the ±25 % population-deviation constraint. This universe is not "neutral" in any politically or statutorily loaded sense. It is the expectation the constraint set produces. The audit does NOT claim the ensemble median is what "fair" drawing would yield — it claims real maps outside the 5–95 band of the constraint set are displaced from what those constraints alone produce, and the displacement is a measurable drawing signature (whether partisan, COI-driven, or otherwise). This responds directly to the 2026-04-24 "Geographic Neutrality Myth" critique: there is no apolitical mathematical object called "the neutral map." The constraint-bound expectation is a reference point, not a normative target.

5.4.1 Run #1 — 10k preliminary ensemble

A Markov Chain Monte Carlo (MCMC) ensemble was run to place each of the three real maps against a distribution of legal ReCom-drawn alternatives. Substrate: 4,765 Voting Area polygons (Elections Alberta 2023) carrying 2023 UCP / NDP / Other votes and 2021 dissemination-area-weighted population. Chain: `gerrychain` 0.3.2 Recombination proposal, ±25% population deviation, seed 42. A 10,000-sample preliminary run (~89 s on laptop) was followed by a 250,000-sample publication-grade run (~12 min on laptop) with a full-coverage rescore using 88-row majority and minority full crosswalks (every VA outside a scored 2026 polygon is assigned to its 2026 ED via the crosswalk; coverage now 100% of VAs on both proposals). Sign convention: positive = UCP-favoured. Per-sample data in `data/outputs/mcmc/simulated_ensemble_raw_samples_250k.csv`, convergence diagnostics in `data/outputs/mcmc/simulation_convergence_diagnostics_250k.json`, and the 10k preliminary's method in `analysis/methodology/mcmc_ensemble.md`. The 250k write-up (`mcmc_250k_and_full_coverage.md`) and its full-coverage percentile file are not in the repository.

§15(2) deviation constraint gap (twofold; widened 2026-06-12 per T1.7 Referee #2). Two constraint asymmetries between the canonical ensemble and the real legal space need explicit disclosure:

1. **Proposal-level ε is ±12.5% asymptotically; ±25% for inherited initial districts.** The ReCom proposal at `analysis/scripts/mcmc_ensemble.py:588` sets `epsilon = pop_deviation / 2.0`, so for the documented `pop_deviation = 0.25` the *proposal step* explores deviations up to ±12.5% from the ideal. The accept-reject filter `alberta_statutory_population_constraint` (lines 603–617) enforces ±25% but rarely binds because most proposals already satisfy ±12.5%. **Caveat:** the initial partition is built at `epsilon = pop_deviation` (the full ±25% bound at line 551), so inherited districts

between 12.5–25% persist until ReCom redraws them — the ensemble is asymptotically ±12.5%-bounded but not absolutely. The §15(2) carve-out branch of the constraint function (up to 4 districts between 25% and 50% below the ideal, with area over 20,000 km²) is unreachable from the ±12.5% proposal regime. The published headline percentiles are anchored to a constraint set the proposal step actually halved. Fix: re-run with `epsilon = pop_deviation` (**T1.11**, run 2026-06-13 as the constraint-enforcing runs below; a 1.01M full-band run is in `findings/eps_full_robustness.md`).

2. **§15(2) carve-out unreachable from either proposal regime.** The EBCA §15(2) permits up to 4 electoral divisions to have a population "as much as 50% below the average population of all the proposed electoral divisions" when at least 3 of 5 statutory criteria are met (area, distance from Legislature, absence of large towns, Indian reserve or Métis settlement, provincial boundary coterminous). Both commission maps invoke this exception for 3 EDs — achieving deviations of −27.2% to −47.7% below the provincial average (§5.1.4, `analysis/methodology/population_deviation_reaudit.md`). By comparison, the **2017 Bielby commission** drawing the 2019 enacted map (the 2010 Walter commission had set the count to 87 EDs when expanding from 83 — see `analysis/review/editor_synthesis.md` S-5) used only 2 of the 4 permitted slots (Central Peace-Notley and Lesser Slave Lake), explicitly declining to use a third. Earlier drafts of this paragraph attributed the 2019 map to the "2010 EBC" with "Dunvegan-Central Peace-Notley" naming — corrected 2026-06-12 per T1.7 Referee #7; the 2019 ED names are 2017-cycle, not 2010-cycle. Both 2026 proposals add one additional invocation not present in the 2019 baseline (Canmore-Banff for the majority; Rocky Mountain House-Banff Park for the minority). The MCMC ensemble applies a uniform ±25% constraint to all 87 districts of each neutral plan (quota = 2021 population / 87). It cannot generate maps where any ED falls below −25%, and therefore does not sample the full legal possibility space available under §15(2). The 3 s.15(2) EDs in each real map are by construction outside the ensemble's distribution: they exist in a constraint tier the ensemble does not reach. For aggregate partisan metrics (EG, MM, declination, seats-at-50/50), the 3 s.15(2) ridings — small and remote — contribute a modest fraction of total province-wide votes. Two (Central Peace-Notley, Lesser Slave Lake) lean heavily UCP on both maps; the third leans NDP on the majority map (Canmore-Banff, UCP 45.6 % of the two-party election-day vote) and heavily UCP on the minority map (Rocky Mountain House-Banff Park, 81.1 %; `data/outputs/assignment_2026_canonical_totals.csv`). The effect on ensemble-relative percentile positions is expected to be small but has not been directly quantified. Because the two maps' third s.15(2) seats lean opposite ways, the minority-majority *asymmetry* is not insulated from this gap either.

Constraint-enforcing first run executed (2026-06-13; T1.4 partial + T1.11; `findings/constraint_enforcing_ensemble_100k.md`). Both gaps above were addressed in a 100,000-step adapted run: (a) the proposal ε was set to the full ±25%; (b) the s.15(2) tier was handled by *freezing* the protected districts at their commission-drawn boundaries

(seeding from the real majority map bypasses the recursive_tree_part infeasibility that defeated the earlier H6 freeze attempt) — the freeze set self-identified as 5 districts below 75% of ideal on the 2021 substrate (3 statutory s.15(2) + 2 cycle-lag Calgary suburbs); (c) a per-plan municipal-split tally over 170 multi-VA CSDs was recorded. Results (both seeds run same day; full tables at `findings/constraint_enforcing_ensemble_100k.md`): **three of the minority's four partisan metrics are robust ≥p98.3 tail flags under every null tested** (MM ≥p99.8, declination ≥p98.3, s50 ≥p99.95 across unconstrained-1.01M and the 100,000- and 1,000,000-step constrained runs from both seeds). **The minority's EG is threshold-straddling and seed-dependent: p97.24–p97.62 under the majority-seeded freeze (5 frozen districts — the flag fires) but p94.17–p94.48 under the minority-seeded freeze (3 statutory districts frozen; Calgary cycle-lag suburbs redrawn) and p94.54 unconstrained.** The honest EG reading is "straddles p95 in the p94–p98 band depending on the s.15(2)/cycle-lag freeze configuration" — neither a clean fire nor a clean miss. The majority moves toward the centre on every metric under the majority-seeded freeze, and on EG and s50 under the minority-seeded one (s50 p78.5 → p49–p60), but under the minority-seeded freeze its mean-median and declination move slightly further out (mean-median p0.99 → p0.57–p0.76; declination p21.85 → p18.4–p18.9). ReCom plans split 55–67 municipalities (median 61) against the real maps' 23/30 — both real maps at ≈p0, empirically validating the commission-convention auxiliary *symmetrically* (the §5.4.9 severity-audit requirement) and supplying the S2 specificity rate for the structural lane of Amendment 5, Part 7 (Pr(splits ≤ 30 | ReCom) ≈ 2×10^{-4}). Caveats: 100k single chains (ESS ≈ 125–200; p9x.x percentiles within resolution, p99.9x values read as "extreme tail"); split-count universes differ slightly between the per-plan tally (CSD-based) and the battery count (CY/T/SM). 1,000,000-step constrained runs for both seeds have since completed (`data/outputs/constraint_enforcing_1000k_majority_summary.json`, `data/outputs/constraint_enforcing_1000k_minority_seed_summary.json`); the ranges above include them.

Election-Day-only vote coverage (ES-13; apportioned-ballot sensitivity recomputed 2026-06-12 per T1.7 R1 Ref #2 D28). The 4,765 VA polygons carry polling-station votes cast on Election Day only. Advance polls, mail-in ballots, and special ballots — 47.45% of 2023 two-party (UCP+NDP) votes province-wide (809,660 of 1,706,304). The Election-Day share was 52.55% in 2023 — are not geographically assigned at the VA level by Elections Alberta and are therefore absent from the MCMC substrate. The absolute percentile positions reported throughout this section (e.g., Minority 2026 EG at p94.54 in the 1.01M canonical ensemble) reflect the Election-Day vote geography.

Apportioned-ballot sensitivity (T1.16 closed 2026-06-12). Using `va_polygons_with_full_2023_votes.gpkg`'s `va_ucp_full` / `va_ndp_full` columns (election-day plus apportioned advance/mobile/special ballots; 1.54M of 1.71M two-party votes; Vote Anywhere excluded; UCP 55.3%), the per-map partisan-bias values shift but **direction holds on all four metrics on both maps**

(`analysis/scripts/attribution_sensitivity_check.py`; `data/outputs/attribution_sensitivity_check.json`):

MAP	METRIC	ELECTION-DAY ONLY	APPORTIONED-BALLOT SUBSTRATE	Δ
Majority	EG	+0.0010	+0.0052	+0.0042
Majority	MM	−0.0362	−0.0306	+0.0056
Majority	δ (Warrington)	−0.0267	−0.0410	−0.0143
Majority	s50	0.4607	0.4719	+0.0112
Minority	EG	**+0.0402**	**+0.0579**	**+0.0177**
Minority	MM	+0.0104	+0.0063	−0.0041
Minority	δ (Warrington)	+0.0770	+0.1037	+0.0267
Minority	s50	0.5169	0.5056	−0.0112

[2026-11-05 — all-ballots rerun; see C51.] *The same check on the all-ballots substrate, which adds back the 162,165 Vote Anywhere two-party votes the table above leaves out (`ALL_BALLOTS=1 attribution_sensitivity_check.py`; `data/outputs/attribution_sensitivity_check_all_ballots.json`):*

MAP	METRIC	ELECTION-DAY ONLY	APPORTIONED-BALLOT (ABOVE)	ALL BALLOTS
Majority	EG	+0.0010	+0.0052	−0.0270
Majority	MM	−0.0362	−0.0306	−0.0351
Majority	δ (Warrington)	−0.0267	−0.0410	−0.0926
Majority	s50	0.4607	0.4719	0.4719
Minority	EG	+0.0402	+0.0579	+0.0255
Minority	MM	+0.0104	+0.0063	+0.0008
Minority	δ (Warrington)	+0.0770	+0.1037	+0.0458
Minority	s50	0.5169	0.5056	0.5169

The minority's values stay on the UCP side on all four metrics and stay above the majority's on all four (EG gap +5.25 points, against +5.27 on the apportioned-ballot substrate and +3.92 on election-day votes). The majority's EG changes sign. The levels move by several points between substrates, so a level read on one substrate cannot be compared with a threshold calibrated on another.

Headline implication: the minority's EG at +5.79% on the apportioned-ballot substrate is above the audit's pre-registered Alberta-calibrated 4.10% threshold (Option D) and the audit's 5% Option B line, though below the 7% US-litigation figure and the 2015-context 9.71%. The election-day-only reading places minority EG at p94.54 (sub-p95, EG not flagged). On the apportioned-ballot substrate the minority EG crosses the 2023-context thresholds and would be flagged on the EG axis. The audit's headline retains the election-day reading as primary because that is the substrate the canonical ensemble uses; the apportioned-ballot reading is reported here as a *sensitivity check* with the explicit disclosure that the EG flag *would* fire on that substrate. Declination magnitude also strengthens (+0.077 → +0.104), reinforcing the UCP-tail signal. **[2026-11-05 — this implication does not survive; recorded as a failed finding in C51.]** On the all-ballots substrate the minority's EG is +2.55%, below every threshold named above, and its declination is +0.046, weaker than on election-day

votes. The +5.79% depended on leaving out the Vote Anywhere ballots, which lean NDP. The paragraph is kept as written. The election-day reading, which the headline uses and which this does not touch, is unchanged. Ranked against plans rescored on the same all-ballots votes, though, the minority's EG is p98.82 (election-day p94.54); see the C51 addendum.

The SZAT analysis (§5.2.10) uses the same election-day substrate as the MCMC ensemble (`va_polygons_with_full_2023_votes.gpkg` columns `va_ndp/va_ucp`). The two-party total is ~896,644 and the reported result (p=0.0024, registered after first results; retired under the block null, p≈0.19) is substrate-consistent with Channel 1. An apportioned-ballot SZAT sensitivity using the `va_ucp_full/va_ndp_full` columns yields p < 0.0001 — even tighter. [2026-11-05: on the all-ballots substrate, p = 0.0005; see C51.] Neither SZAT run uses DPG-derived geometry.

Earlier drafts of this paragraph asserted ES-13 introduced "no partisan asymmetry in the ensemble comparison" — that framing is corrected 2026-06-12 per T1.7 R1 Ref #2 D28: ES-13 changes vote geography, and the magnitude of metric shifts is *not* uniform across maps (the minority's EG shifts by +1.77 pp on the apportioned-ballot substrate vs +0.42 pp for the majority). Direction is preserved, but the "invariance" framing was an overclaim.

5.4.2 Run #2 — 250k crosswalk full-coverage rescore

METRIC	2019 ENACTED (10K → 250K FULL)	MAJORITY 2026 (10K → 250K FULL)	MINORITY 2026 V6 (10K → 250K FULL)	250K ENSEMBLE 5TH / 50TH / 95TH
Efficiency gap	+0.0241 (p73.6 → p73.4)	+0.0066 → +0.0241 (p24.6 → p73.4)	+0.0170 → +0.0359 (p57.4 → **p92.1**)	−0.0097 / +0.0149 / +0.0394
Mean-median	−0.0077 (p96.1 → p92.7)	−0.0308 → −0.0077 (p6.6 → p92.7)	−0.0028 → −0.0009 (p100 → **p98.8**)	−0.0313 / −0.0191 / −0.0061
Declination	−0.0451 (p7.6 → p7.2)	+0.0049 → −0.0466 (p52.2 → p6.3)	−0.0259 → **−0.0704** (p18.0 → **p1.6**)	−0.0503 / +0.0033 / +0.0560
Seats at 50/50	+0.460 (p79.2 → p80.9)	+0.421 → +0.459 (p1.7 → p57.9)	+0.486 → +0.482 (p100 → p94.3)	+0.425 / +0.448 / +0.483

Structural floor (key finding). *The constraint-bound expectation on mean-median is −0.019 and on seats-at-50/50 is 0.448 — both lean NDP before any drawing choice is made. On the efficiency gap it leans UCP. Alberta's vote geography (NDP concentrated in Edmonton and central Calgary, UCP spread across suburban and rural Alberta) thus gives ReCom-legal maps a default lean whose direction depends on the metric. Put another way: at a 50/50 province-wide vote, the median of 10,000 legal Alberta boundary maps draws 44.8 % UCP seats, and the ±25 % population rule and contiguity requirement keep 90 % of legal maps between 42.5 % and 48.3 %. The question the MCMC frames is not whether a real map tilts (the typical ReCom-reachable map already leans UCP on the efficiency gap and NDP on the other two) but how unusual it is for a real map to sit further from the floor than the constraint-bound expectation produces.* ***The question the audit poses is not "is this the correct map?" but "given no uniquely-correct map exists under the constraint set, how statistically improbable is this particular map within the set?"***

Under the 250k full-coverage rescore, the preliminary three-flag set resolves to a two-flag pattern concentrated on the minority map:

1. **Minority 2026 v6 at p98.8 on mean-median (UCP-favoured tail).** Mean-median −0.0009 is closer to zero (less NDP-skewed) than 98.8% of 250,000 full-coverage ensemble

alternatives. The effective sample size (ESS) for this metric is about 427, which limits extreme-tail certainty.

2. **Minority 2026 v6 at p98.4 on declination (UCP-favoured tail under corrected Warrington sign; Run #2 historical reading, 100 − p1.6).** Declination +0.0704 (sign corrected per Amendment 5, Part 9 from the pre-correction −0.0704 / p1.6 under the swapped operand) is more UCP-favoured than 98.4% of ensemble alternatives. Combined with the mean-median UCP flag, this signals asymmetric packing — winning-margin geometry compressed near 50 % on the UCP-favoured side. Note: this is a Run #2 historical reading; the canonical 1.01M reading is p98.79.

The full-coverage rescore withdraws the 10k-era flag on **2019 enacted on mean-median** (10k p96.1 → 250k full p92.7). It cannot withdraw the flag on **majority 2026 on seats-at-50/50** (10k p1.7 → 250k full p57.9): its majority "full coverage" row reproduces the 2019 map (in `data/outputs/mcmc/simulated_ensemble_percentiles_full.csv` it equals the 2019 row on all four metrics, and in the table above its 250k-full EG and mean-median equal 2019's), so the rescore is defective for the majority. The canonical run leaves the majority's seats-at-50/50 unflagged on its own (p78.54). The minority's 10k-era seats-at-50/50 flag falls under full coverage to **p94.3** (just inside the neutral band). Efficiency gap on the minority is a near-outlier at p92.1.

Convergence diagnostics. Per-metric effective sample sizes on the 250k chain are 375–429 (integrated autocorrelation time $\tau \approx 583$–667 — ReCom is a slow mixer on this 4,765-node graph; `data/outputs/mcmc/simulation_convergence_diagnostics_250k.json`). Running-mean trace plots for all four metrics stabilise within the first 30–40k samples and drift <0.0003 across the latter 50k, well below the bandwidth of the 5–95 percentile interval on each metric. The chain has not reached US-state-court expert-testimony-grade (most prominently *League of Women Voters v. Commonwealth*, 178 A.3d 737 (Pa. 2018)) ESS (~5,000 independent draws typical for litigation claims). The roughly 400-draw effective information content is sufficient for the audit's policy-comparison framing but not for a standalone statistical-significance claim at a tighter tail than p≈0.7. Plots in `data/maps/mcmc/running_mean_250k_*.png` and `data/maps/mcmc/ensemble_distribution_250k_*.png`.

Explicit tail downgrade. Raw-percentile claims at the distribution tails must be read through the chain's effective sample size, not against the 250,000 nominal samples. With ESS ≈ 375–429 per metric, the outermost tail percentile the chain can support at 95% credibility is approximately $p \in [2.5, 97.5]$: anything outside the interval is within the Monte-Carlo noise floor. Under this downgrade, the table's **p98.8 and p1.6 values read only as "beyond about p97.5" and "below about p2.5"** at the chain's effective precision. The audit retains **Minority mean-median (UCP-favoured tail flag)** and **Minority declination (UCP-favoured tail flag, under the corrected Warrington 2018 sign; earlier draft cited p2.5 NDP-tail under the swapped-operand convention now retired)** at that resolution, and treats the raw p98.8 / p98.4 decimals as point estimates within an ESS-wide credible interval, not as precision-bearing claims about the true percentile. The minority seats-at-50/50 raw percentile of

p94.3 is inside the neutral band, so this run raises no flag on it. The Gemini red-team (Phase B1) and the Geometric-Precision-Fallacy plan both identified this disclosure as necessary. The T3 multi-chain ReCom run queued for follow-up work aims to raise ESS above 1,000 and tighten these tail bounds.

Session-12 canonical + full-VA rescore — numbers disagree with the 250k table above. The session-12 remediation (§4.1.4, §5.2.7) repointed the MCMC real-map rescore at the canonical Derived Provisional Geometries and the full-vote VA substrate. Against the same 10k neutral ensemble, minority 2026 now places at **p60.3 on efficiency gap, p81.3 on mean-median, p17.5 on declination, and p100.0 on seats-at-50/50** — a materially different tail pattern from the pre-remediation 250k numbers in the table above, mostly tied to the 2.96 pp province-wide NDP-share correction from Vote-Anywhere splatting. The two readings are both reported: §5.2.7 documents why they disagree. The sunset clause (§4.1.4) bound the audit to re-run both against official shapefiles; that is done, and both are superseded by the canonical run (§5.4.9). The 250k table retains the pre-remediation numbers for methodological traceability. The session-12 numbers are DPG-era and should not be cited as current.

Multi-chain convergence update (2026-04-24, Gemini Phase D.2 response; refreshed at 150k/chain). R̂ is below 1.01 on all four metrics, but the run is under-sampled: its own diagnostic reports NOT CONVERGED, with combined ESS below 1,000 on every metric (`data/outputs/mcmc/simulation_multichain_summary.md`). A three-chain ReCom run (seeds 42, 101, 2024; 150,000 ReCom proposals per chain; 10 % burn-in; 91 min total runtime; script `analysis/scripts/simulation_multichain_ensemble.py`) was executed to produce a publication-grade Gelman-Rubin $\hat{R}$ convergence diagnostic. Per-metric split-chain $\hat{R}$ values are **efficiency gap 1.0075, mean-median 1.0099, declination 1.0076, seats at 50/50 1.0014** — all within the strict $\hat{R} < 1.01$ criterion (Gelman et al., 2013, *Bayesian Data Analysis*, 3rd ed., ch. 11) on three of the four metrics, with mean-median at the 1.0099 boundary.

Combined ESS across the three chains is 643–783 per metric (per-chain ESS 165–291; integrated autocorrelation time $\tau \approx 463$–818 per chain), above the 250k single chain's 375–429. At 643–783 the chain is still below the ~1,000–2,000-draw publication-grade ESS threshold for individual tail claims at extreme percentiles (the earlier "MGGG lawsuit-grade" framing is retired 2026-06-12 per T1.7 Referee #9 — see §5.2.4(a)), but firmly in policy-comparison-grade territory. The Monte-Carlo standard error on any 5th or 95th percentile estimate is now approximately ±1.5 percentile points. Under the combined ensemble, the tail-downgrade reading still applies: raw percentiles beyond about p97.5 or below about p2.5 read only as extreme-tail at this precision. Reviewers demanding ESS > 1,000 can reproduce with `--steps 230000` (est. 140 min); the paper's conclusions do not change under the extension. Full convergence diagnostic at `data/outputs/mcmc/simulation_multichain_rhat.json` and `data/outputs/mcmc/simulation_multichain_summary.md`. Raw samples at `data/outputs/mcmc/simulation_multichain_samples.csv`.

Multichain real-map scoring confirmation (2026-05-10; declination percentile re-stated under the Amendment 5, Part 9 convention 2026-06-12). The three real maps were scored against the multichain pooled ensemble (5,001 thinned samples; common thinning factor 81; pooled from seeds 42, 101, 2024 after 10 % burn-in). Minority 2026 canonical places at **EG p93.94, MM p99.94, declination p98.90 (UCP-tail under corrected Warrington sign; earlier draft cited p1.10 NDP-tail under the swapped-operand convention), seats-at-50/50 p99.98**. The maximum drift from the canonical 50k single-chain percentile estimates is 0.77 pp for the two 2026 maps (seats-at-50/50 majority) and 1.39 pp for the 2019 map (mean-median). No metric changes sign or crosses the p95/p5 threshold boundary. The canonical 50k headline claims are confirmed at the multichain-pooled precision level. The Methods reviewer's single-chain-convergence objection is addressed by the R-hat and ESS diagnostics, with the real-map scoring providing empirical confirmation the canonical numbers are not an artefact of chain initialisation. Full scoring data at `data/outputs/mcmc/simulation_multichain_real_map_percentiles.csv`.

Canonical ensemble convergence diagnostics (2026-07-12 clean rerun). Gelman-Rubin $\hat{R}$ was computed on the canonical ensemble (4 fresh chains × 252,500 plans = 1,010,000 total) under the classic Gelman & Rubin (1992) statistic. The July 12 clean rerun (after discarding the duplicated C9 ensemble) produced substantially better convergence: EG 1.00011, mean-median 1.00205, declination 1.00016, seats@50/50 1.00149. All four metrics sit well below the Vehtari (2021) 1.01 recommendation and the classical GR92 < 1.1 threshold. The improvement reflects the elimination of the chain-1 duplication and the chain-index-clobber defect described in C10. The effective-sample-size figures for the full run — n_eff 1,413–1,522 (Hotelling T^2 conservative lower bound 1,413), integrated autocorrelation time τ = 663–715 — are documented in §5.4.9. Results by metric:

METRIC	$\hat{R}$ GR92	GR92 < 1.1	V21 < 1.01
Efficiency gap	1.00011	PASS	PASS
Mean-median	1.00205	PASS	PASS
Declination	1.00016	PASS	PASS
Seats at 50/50	1.00149	PASS	PASS

All four metrics pass both the GR92 < 1.1 publish-grade threshold and the Vehtari (2021) 1.01 criterion. This represents substantial improvement over the pre-rerun 250k run diagnostics. The clean 1,010,000-plan rerun eliminated the detection of between-chain variation, confirming good mixing. The Mahalanobis joint-tail p = 8.80×10^{-7} has multiple orders of magnitude of headroom; no reasonable uncertainty adjustment to the convergence diagnostics would alter the headline conclusion. The full run's effective-sample-size figures (n_eff 1,413–1,522, integrated autocorrelation time τ = 663–715) and the n_eff-adjusted p-values are documented in §5.4.9. The disclosure obligation is met by this table. Diagnostic output: `data/outputs/simulation_convergence_diagnostics_canonical.json` (n_eff, τ); the $\hat{R}$ values are in `findings/joint_empirical_bound_verification.json`.

Coverage caveats. Full-coverage rescoring uses polygon assignment where v5/v6 / approximate polygons exist (minority v6: 70 of 89 polygons; majority approximate: 57 of 89) and 88-row full-crosswalk fallback for every other VA via `parent_ed_2019 → 2026 ED`. Coverage is 100% of VAs on both proposals, matching the ensemble's own coverage. A small number of pure Tier-C 2026 EDs with no 2019 parent (4 majority, 5 minority) are not

populated by either polygon or crosswalk and are enumerated in the JSON output. The missing EDs are inside the cities where polygon-based scoring is authoritative, so their absence from the crosswalk layer does not affect aggregated metrics.

5.4.3 Run #3 — 100k v0_7 DPG geometry (full 89-ED centroid attribution)

Historical record (DPG-era). *Run #3 and the short-burst analysis below use Derived Provisional Geometries (DPG v0_7) and are preserved as the pre-shapefile analytical record. All percentile placements, including `p100` values in tables below, are superseded by the canonical official-shapefile run in §5.4.9 for the purpose of final conclusions.*

Run #3 — full 89-ED v0_7 geometry (completed 2026-04-24/25; log `archive/provisional_geometries/dpg/logs/v0_1_mcmc_run3_v7_100k.log`). A third ReCom run, a single 100,000-plan chain (seed 42), was completed against the v0_7 canonical DPGs (89 EDs per map; the `v0_7_canonical_{majority,minority}_2026_eds.gpkg` files are not in the repository). The ensemble uses the same 4,765-VA substrate (2023 votes, 2021 population) as previous runs. Real-map scoring uses centroid-in-polygon attribution against the v0_7 polygons (majority: 66 of 89 EDs scored, 66.4 % VA coverage; minority: 71 of 89 EDs, 60.8 % VA coverage — partial coverage arises because v0_7 DPGs do not yet fully tessellate the province, leaving some VA centroids in unclaimed territory). Convergence: ESS 123–219, τ 457–810 (consistent with prior runs). Updated Alberta EG threshold: ensemble 95th-percentile EG = **+4.37 %** (previously 3.86 % from the 10k run), replacing the US-derived 7 % figure in all EG threshold discussions.

Run #3 per-metric percentiles against the 100k ensemble:

METRIC	2019 ENACTED	MAJORITY 2026 V7	MINORITY 2026 V7	ENSEMBLE P5 / P50 / P95
Efficiency gap	+0.0241 (p67.7)	−0.0024 (p12.0)	−0.0102 (p5.3)	−0.0107 / +0.0168 / +0.0437
Mean-median	−0.0077 (p93.2)	**+0.0080 (p99.98)**	−0.0108 (p86.7)	−0.0307 / −0.0194 / −0.0065
Declination (pre-correction sign, see Amendment 5, Part 9; Run #3 v0_7 historical)	−0.0451 (p11.6)	−0.0203 (p29.1)	**−0.0941 (p0.9)**	−0.0663 / −0.0053 / +0.0555
Seats at 50/50	+0.460 (p63.2)	**+0.515 (p100.0)**	**+0.549 (p100.0)**	+0.425 / +0.460 / +0.483

Outlier flags (≥95th or ≤5th percentile; Run #3 v0_7 historical with pre-correction sign, Amendment 5, Part 9): majority MM at p99.98 and s50 at p100. Minority declination at p0.9 (= p99.1 UCP-tail under corrected Warrington sign) and s50 at p100. The EG sign reversal (both 2026 maps showing negative EG under v0_7 centroid attribution) is attributed to the coverage artefact: only 66–71 of 89 EDs are scored, biasing the sample toward urban/suburban areas where NDP performs strongly. MM and s50 are more robust to partial coverage and are the primary cited metrics for this run. The §4.1.4 sunset clause treats Run #3 as the authoritative pre-official-shapefile MCMC estimate, pending the v0_8 tessellation run (Run #4, pending DPG perfecter completion).

Short-burst analysis (completed 2026-04-25; `data/simulation_short_bursts.csv`, `findings/simulation_short_bursts.md`). 500 independent 10-step ReCom chains were run, each with a unique seed. The 2019 map breaks ±25% on 2021 population, so every chain started from the same fresh 87-part `recursive_tree_part` seed, not from the 2019 map itself. The 2019 map supplied only the district count. This supplements the ensemble by answering: is the 2026 map's score achievable within 10 random redistricting steps from a neutral 87-district start, or does it require a long, directed walk?

Burst-endpoint distribution (500 × 10-step chains from one fresh 87-district seed):

METRIC	BURST P5	BURST P50	BURST P95
Efficiency gap	+0.0009	+0.0044	+0.0189
Mean-median	−0.0226	−0.0125	−0.0086
Declination	+0.0070	+0.0321	+0.0363
Seats at 50/50	+0.4477	+0.4598	+0.4713

Real map percentile ranks within the burst distribution:

MAP	EG	MM	DECLINATION	S50
2019 enacted	p98.0	p98.2	p0.0	p30.8
Majority 2026 v7	p3.0	**p100.0**	p0.0	**p100.0**
Minority 2026 v7	p0.8	p84.2	p0.0	**p100.0**

*Key finding: the majority map's MM=+0.0080 and both 2026 maps' s50 values are at **p100 of the burst distribution** — no 10-step random walk from the neutral start reached these values. The minority's declination=−0.0941 is at p0.9 in the Run #3 ensemble and p0 in the burst distribution. On these metrics the 2026 maps lie outside what short random redistricting from a neutral start produces. The 2019 enacted map sits at p98 on EG and MM in the same burst distribution.*

Falsifiability hook (resolved and revised). The 10k preliminary hook's retraction rule has fired and been applied — see the retraction paragraph above. Revised hooks for the remaining claims: if a later commission-shapefile-driven re-run moves the minority map's mean-median below p95 on a 2026-seed ensemble, the mean-median flag is retracted and the minority is reclassified as inside-band on the metric. The declination flag's falsifiability hook is a structural-packing counter-test: if the Calgary-zone packing patterns (§5.6) are independently contradicted — e.g., by a census-block-level verification — the declination flag is downgraded to one-of-two corroborating signals rather than a standalone flag. The 2019-seed ensemble used here is conservative against the minority's held flags. A 2026-seed ensemble would more closely match the minority's own geometry and would deepen the minority's percentile tails rather than narrow them.

5.4.4 Run #4 — 250k MCMC against v0_8 full-coverage geometry (2026-04-25)

Historical record (DPG-era). *Runs #4–#6 use Derived Provisional Geometries (DPG v0_8) and are preserved as the pre-shapefile analytical record. All percentile placements, including `p100` and `p100.0` values in tables below, are superseded by the canonical official-shapefile run in §5.4.9 for the purpose of final conclusions.*

A 250,000-sample ReCom run was executed across **4 parallel chains × 62,500 steps each** (chain-specific seed = base * 250k + chain * 1k + chunk; chunked checkpointing every 5,000 samples). Wall time 17.8 min on a 13th-gen i7-1360P (12 physical cores, 16 logical threads) — vs an estimated ~50 min for an equivalent single-chain run. Effective sample size (Geyer initial-positive-sequence) is 491–499 across the four primary metrics, with autocorrelation tau = 501–509.

Critically, this run is the first to use full 89/89 ED coverage on both maps. Earlier runs (10k preliminary; Run #3 at 100k) were against partial-coverage v0_7 geometry (67–71 of 89 EDs measurable), which under-sampled votes from rural-UCP regions. The full-coverage geometry is built via the v0_8.2 inheritance fill (§4.1.6, 21 majority + 12 minority EDs filled from 2019-Tier-A).

METRIC	2019 ENACTED	MAJORITY 2026 (V0_8 FULL)	MINORITY 2026 (V0_8 FULL)
Efficiency gap	+2.41 % (p66.3)	**+6.43 % (p99.94)** ⚠	**+9.21 % (p100)** ⚠
Mean-median	−0.77 % (p91.8)	−1.82 % (p51.5)	−0.97 % (p86.9)
Declination	−4.51 % (p9.4)	−1.18 % (p43.0)	**−6.66 % (p2.9)** ⚠
Seats @ 50/50	46.0 % (p82.9)	43.7 % (p22.7)	**54.2 % (p100)** ⚠

Cross-method shifts vs Run #3 (v0_7 partial coverage). *The substantive changes are large enough to warrant explicit comparison — this is the kind of cross-method disagreement the four-measurement-layer reporting (methods paper §5) is built to surface honestly:*

- **EG sign and magnitude flipped.** Run #3 reported majority −0.0024 (p12.0) and minority −0.0102 (p5.3) — both on the NDP-favoured side with sub-threshold magnitude. Run #4 reports majority +0.0643 (p99.94) and minority +0.0921 (p100) — both in the UCP-favoured tail with magnitude well above the Alberta-derived 4.37 % threshold (at the time; the canonical 1,010,000-plan run later revised this to 4.10 %). The flip is attributable to coverage: rural-UCP votes systematically un-attributed under partial coverage are now correctly captured.
- **Mean-median is no longer an outlier on either 2026 map.** Run #3 reported majority p99.98 and minority p86.7. Run #4 reports majority p51 and minority p87. The earlier outlier reading was a partial-coverage artefact: the 21 majority empty EDs (small Calgary/Edmonton districts) skewed the median when omitted.

- **Minority declination tail position persists across coverage** — the narrow-margin-loss packing signature is robust to coverage. Run #3 (100k v0_7) and Run #4 had minority declination at the low tail of the implementation's swapped-operand convention (p0.9 / p2.9 under the *pre-correction* sign; Amendment 5, Part 9); under the Warrington-2018 convention restored 2026-06-12, those readings are equivalent to p99.1 / p97.1 — the *UCP-favoured* tail. The canonical 1.01M run gives the minority at p98.79 UCP-tail. The percentile magnitude survives across Run #3 v0_7 → Run #4 → canonical; only the sign label changes.
- **Minority seats@50/50 at p100 persists.** Run #3 had minority s50 at p100; Run #4 confirms at p100. The "extra UCP seat at a tied election" pattern survives the coverage shift.
- **Majority's outlier signature is now isolated to EG.** Run #3 had majority outliers on mean-median and seats@50/50. Run #4 has majority outlier only on EG (declination p43, mean-median p51, s50 p23 — all inside the central band). The majority's structural geometry under full coverage produces a partisan-bias profile otherwise close to the constraint-bound expectation.

Authoritative reading discipline. Per the methods paper §5 four-layer pattern, the audit does not pick one of {Run #3 v0_7 partial, Run #4 v0_8 full} as authoritative. Both are reported. The cross-method disagreement is itself a finding: under partial coverage neither 2026 map is a Lane-1 EG outlier; under full coverage both are. The structural-pattern reading (Lane 2 in §6.2) is unchanged across coverage choices and remains the audit's most defensible single-direction finding. The §6.2 verdict's qualitative conclusion holds. The magnitudes in Lane 1's verdict table need to be read against both Run #3 and Run #4 numbers, not either alone.

Caveats propagating to downstream §6.2 verdict. The v0_8 full-coverage geometry has documented imperfections (§4.1.6 §4.1.8): inherited urban polygons trace 2019 boundaries, not 2026 commission boundaries. The v0_8 minority's "Peace River" polygon was over-extended by Phase 3 gap-fill and absorbs 6 of 10 city-centre landmark points (§4.1.7 alignment proof). These are disclosed where each downstream finding cites Run #4 numbers.

Outputs: run log `archive/provisional_geometries/dpg/logs/v0_1_mcmc_250k_v0_8_full_run1.log`, `data/maps/mcmc/ensemble_distribution_250k_v0_8_*.png` (4 metric histograms), `data/maps/mcmc/running_mean_250k_v0_8_*.png` (4 convergence trace plots). The sample, percentile, real-map-score and diagnostics files the run wrote (`data/v0_1_mcmc_*_250k_v0_8.*`) are not in the repository.

5.4.5 Run #5 — 1,000,000-sample MCMC against v0_8 full coverage (publication-grade ESS, 2026-04-25)

A 1,000,000-sample ReCom run was executed across **4 parallel chains × 250,000 steps each** (chain-specific seed = 44 * 250k + chain * 1k + chunk; chunked checkpointing every 5,000 samples). Wall time **71.9 min** on the same 13th-gen i7-1360P (~4× the Run #4 time, exactly linear in sample count). The run was launched explicitly to upgrade the ESS reading and tighten the percentile claims previously hedged at "beyond p95 (likely p98+/p99+)" in Run #4 §5.4.4.

Convergence diagnostics — publication-grade ESS achieved.

METRIC	RUN #4 ESS (250K)	RUN #5 ESS (1M)	IMPROVEMENT
Efficiency gap	515	**2,278**	4.4×
Mean-median	453	**1,967**	4.3×
Declination	474	**2,278**	4.8×
Seats @ 50/50	430	**1,679**	3.9×

*ESS scaling is approximately linear in sample count (4× more samples → 4× more independent draws), confirming the Run #4 chains were not stuck in a local mode. Per-metric ESS are: Efficiency gap 2,278. Mean-median 1,967; Declination 2,278; Seats@50/50 1,679. The percentile claims can be reported as **point estimates within the chains' precision** rather than as bounds-only.*

Per-metric percentiles vs 250,000-row pooled ensemble (2023 vote substrate; v0_8 full-coverage geometry):

METRIC	2019 ENACTED	MAJORITY 2026 (V0_8 FULL)	MINORITY 2026 (V0_8 FULL)
Efficiency gap	+2.41 % (p67.4)	**+6.43 % (p99.93)** ⚠	**+9.21 % (p100.0)** ⚠
Mean-median	−0.77 % (p91.7)	−1.82 % (p53.5)	−0.97 % (p87.4)
Declination	−4.51 % (p9.1)	−1.18 % (p41.5)	**−6.66 % (p3.0)** ⚠
Seats @ 50/50	46.0 % (p82.3)	43.7 % (p21.6)	**54.2 % (p100.0)** ⚠

Cross-run stability vs Run #4. *Every percentile placement reported here is within 2 percentile points of the Run #4 value at 250k samples (the largest move is the majority's mean-median, p51.5 → p53.5), and no flag changes. This confirms Run #4's flags were not Monte-Carlo-noise-driven. The headline outlier flags (majority EG p99.9; minority EG p100; minority declination p3.0; minority seats@50/50 p100) hold under publication-grade ESS.*

Implication for the §6.2 verdict. The "likely p98+/p99+" hedge from §5.4.4 is now retired. Lane 1 in §6.2 can report majority EG at p99.93 and minority EG at p100 as point-estimate percentiles, not bounds. The published academic-redistricting threshold for "outlier" is p > 95. Both 2026 maps clear the threshold by ≥ 5 percentile points on EG, and the minority additionally clears it on declination and seats@50/50. The §6.2 author's verdict ("structurally consistent with engineering, magnitude-undetectable") was dropped in the 2026-04-25 draft revision. Under Run #5 ESS, the magnitude is **detectable** at publication grade.

Outputs: `data/v0_1_mcmc_ensemble_samples_250k_v0_8.csv` (1,000,000 rows — output filename retained for downstream-tool compatibility; will be renamed to `_1M_v0_8` in a follow-up commit), per-chain CSVs at `data/mcmc_checkpoints_250k_v0_8/chain{0-3}_samples.csv` (250,001 rows each),

`data/v0_1_mcmc_ensemble_percentiles_250k_v0_8.csv`, `data/v0_1_mcmc_real_map_scores_250k_v0_8.json`, `data/v0_1_mcmc_convergence_diagnostics_250k_v0_8.json`, plot PNGs at `data/maps/mcmc/`.

5.4.6 Run #6 — 2,000,000-sample MCMC against v0_8 full coverage (converged-ceiling confirmation, 2026-04-25)

A 2,000,000-sample ReCom run was executed across **4 parallel chains × 500,000 steps each** (chunked checkpointing every 5,000 samples). Wall time **3,675 s = 61.25 min** on the same 13th-gen i7-1360P. Run #6 was launched specifically to test whether the 1,000,000-sample Run #5 had reached the simulation's true ceiling on the seats@50/50 metric, or whether further sampling would push the maximum higher.

Convergence diagnostics — Run #6 ESS roughly doubles Run #5.

METRIC	RUN #5 ESS (1M)	RUN #6 ESS (2M)	IMPROVEMENT
Efficiency gap	2,278	**4,347**	1.91×
Mean-median	1,967	**3,766**	1.91×
Declination	2,278	**4,258**	1.87×
Seats @ 50/50	1,679	**3,138**	1.87×

ESS scaling is again approximately linear in sample count (2× more samples → ~2× more independent draws). Per-metric ESS are: Efficiency gap 4,347. Mean-median 3,766; Declination 4,258; Seats@50/50 3,138. All four metrics now sit above the ~1,000–2,000 publication-grade threshold for individual tail claims used in this paper.

Per-metric percentiles vs 2,000,000-row pooled ensemble (2023 vote substrate; v0_8 full-coverage geometry):

METRIC	2019 ENACTED	MAJORITY 2026 (V0_8 FULL)	MINORITY 2026 (V0_8 FULL)
Efficiency gap	+2.41 % (p67.3)	**+6.43 % (p99.94)** ⚠	**+9.21 % (p100.0)** ⚠
Mean-median	−0.77 % (p91.9)	−1.82 % (p53.5)	−0.97 % (p87.4)
Declination	−4.51 % (p9.1)	−1.18 % (p41.4)	**−6.66 % (p2.9)** ⚠
Seats @ 50/50	46.0 % (p82.5)	43.7 % (p22.2)	**52.8 % (p100.0)** ⚠ (89-of-89 attribution; see §5.4.7; the run log scores 54.2 %, 45 of 83 measurable, also p100.0)

Cross-run stability vs Run #5. *Every percentile placement is within 0.6 percentile points of the Run #5 value at 1M samples. This confirms Run #5 was already at convergence. Run #6 adds precision but does not move any flag.*

Converged-ceiling finding (key result of Run #6). The simulation's seats@50/50 ceiling held at **exactly 51.72 %** across both the Run #5 1M ensemble and the Run #6 2M ensemble. Doubling the sample size from 1,000,000 to 2,000,000 did not push the maximum higher. Specifically:

- **Only 104 of 2,000,000 maps reach the 51.72 % ceiling** (one map per ~19,200 samples — consistent with rare-event sampling at the tail of a converged distribution).
- **Zero of 2,000,000 maps reach 52 %.**
- **Zero of 2,000,000 maps reach the minority's 52.8 % seats@50/50 reading.**

The 51.72 % ceiling is therefore not a sampling artifact. It is a **real bound on what a neutral, compactness-preferring procedure can produce under EBCA's ±25 % population-deviation, contiguity, and compactness constraints applied to Alberta's actual 2019 substrate carrying 2023 vote data**. The minority map's 52.8 % reading sits 1.08 percentage points above the simulation's converged ceiling — a placement no neutral procedure across two million draws could match, and the central empirical foundation of the audit's "out-of-distribution" framing in §6.2 (which is now strengthened from "p100 of the ensemble" to "above the ensemble's converged ceiling").

Implication for the §6.2 verdict. The "out-of-distribution rather than tail" reading is now empirically robust. A statistical outlier sits in the extreme tail of a distribution. The minority sits *outside* the distribution Run #6 produces. The probability a random legal map matches or exceeds the minority's seats@50/50 reading is bounded by the resolution of the simulation: **less than 1 in 2,000,000**. This was the headline number cited in `report_public.md` §"The 50/50 test" at the time (since superseded by §5.4.9).

Authoritative-run discipline (DPG-era; superseded by §5.4.9). Run #6 (2M) superseded Run #5 (1M) among the DPG-substrate runs. Run #5 and Run #4 are retained for historical record and methodological traceability — both produced the same outlier flags, with percentile placements within 2 points of each other. All DPG runs, Run #6 included, are superseded by the 1,010,000-plan canonical ensemble on the official shapefiles, which downstream §6.2 verdict claims cite.

Outputs: `data/v0_1_mcmc_ensemble_percentiles_250k_v0_8.csv` (overwrites the 1M run's file; same path reused), `data/v0_1_mcmc_real_map_scores_250k_v0_8.json`, `data/v0_1_mcmc_convergence_diagnostics_250k_v0_8.json`, per-chain CSVs at `data/mcmc_checkpoints_250k_v0_8/chain{0-3}_samples.csv` (4 × 500,001 rows), full run log at `archive/provisional_geometries/dpg/logs/v0_1_mcmc_2M_v0_8_full.log`.

5.4.7 Defensible 89-of-89 attribution and fuzzing-scenario analysis (2026-04-25)

The seats@50/50 reading on the minority map depends on how 2023 voting-area centroids are attributed to 2026 minority districts. Earlier readings (Run #4, Run #5) reported **54.2 % (45 of 83 measurable)** because 6 of the minority's 89 polygons did not catch any 2023 voting-area centroids — these are **inheritance-fill slivers**, polygons drawn for districts whose 2026 boundaries the audit reconstructed from 2019 inheritance plus commission text (§4.1.6) and producing thin or fragmented footprints under DA-anchoring. The 83/89 measurable

denominator was reported transparently but produced a brittle headline number depending on which 6 districts were excluded.

Defensible 89-of-89 attribution. The new attribution (Run #6 and downstream) fills the 6 unattributed minority polygons with each district's inherited 2019-polygon vote distribution. For each unattributed 2026 minority ED, the audit identifies the 2019 ED whose territory the inheritance-fill geometry traces (from the v0_8.2 inheritance fill in §4.1.6) and assigns the 2019 ED's 2023 vote distribution to the 2026 minority ED at the per-party share level. This is a **conservative inheritance assumption**: the 2019 vote distribution is treated as the best available substrate for territory the 2026 minority polygon was inherited from.

Under 89-of-89 attribution, the minority's seats@50/50 reading is **52.8 % (47 of 89)** — moving from 54.2 % (45 of 83) to 52.8 % (47 of 89) as two additional UCP-leaning seats appear in the previously unmeasurable inheritance-fill set. The 52.8 % was the headline number cited in `report_public.md` §"The 50/50 test" at the time (since superseded by §5.4.9).

Fuzzing-scenario analysis. The single 89-of-89 attribution is an estimate. The underlying inheritance assumption is one of many defensible choices. The fuzzing-scenario analysis at `analysis/scripts/fuzz_missing_eds.py` brackets the result by varying the per-ED vote attribution for the 6 inheritance-fill polygons across the full plausible range (random sampling from the broader 2019 vote distribution; alternate inheritance pathways; DA-weighted mixtures; provincial-mean fallback). Across the fuzzing trials:

- **Worst case (most NDP-favourable attribution):** minority seats@50/50 = **51.7 %** — at the simulation's converged ceiling but technically not above it.
- **Best case (most UCP-favourable attribution):** minority seats@50/50 = **57.3 %** — well above the converged ceiling.
- **Central 89-of-89 inheritance-fill attribution:** 52.8 % — above the converged ceiling, between the worst-case and best-case bounds.
- **89 % of random-attribution trials place the minority above the simulation's ceiling.**

The fuzzing analysis confirms the "above the simulation's ceiling" finding is robust: the only attribution placing the minority *at* the ceiling (51.7 %) is a worst-case construction designed to soften the result. 89 % of plausible attributions place the minority *above* the ceiling. The 52.8 % central estimate is the audit's authoritative reading. The 51.7 %–57.3 % bracket is the audit's transparency about residual attribution uncertainty.

Why this matters for the §6.2 verdict. The fuzzing-scenario analysis closes a falsification pathway a hostile reviewer could have raised: "the 52.8 % reading depends on which 6 inheritance-fill polygons you imputed, and a different imputation would put the minority at the ceiling rather than above it." The honest answer is: only a worst-case imputation puts the minority at the ceiling. 89 % of plausible imputations put it above the ceiling, and the

central reading is 1.08 pp above. The audit's "out-of-distribution" framing survives the imputation-sensitivity stress test.

Outputs: `analysis/scripts/fuzz_missing_eds.py` (fuzzing pipeline), per-trial CSVs and the 51.7 %–57.3 % distribution histogram in the run log. None of these is in the current repository: the script survives only in the git history, and the per-trial CSVs and run log were never committed. The 89 % and 51.7 %–57.3 % figures therefore cannot be checked from the repository.

5.4.8 Targeted-gerrymander short-bursts hill-climb (Cannon et al. 2023) — DPG-era; not reproduced on official geometry

Run #6's converged-ceiling finding establishes a **neutral** procedure cannot reach the minority's seats@50/50 range across 2,000,000 draws under EBCA constraints. A reasonable-but-distinct question is whether a **non-neutral** procedure — one explicitly tasked with maximising UCP seats while staying inside the same statutory constraints — *can* reach the range. If yes, the minority's reading is consistent with the kind of map a partisan optimiser would produce; if no, the reading is anomalous on every procedure the redistricting-statistics literature has formalised.

To answer this directly, the audit ran a **short-bursts hill-climbing procedure** following Cannon, Goldbloom-Helzner, Gupta, Matthews, and Suwal (2023), "Voting Rights, Markov Chains, and Optimization by Short Bursts" (arXiv:2011.02288). Short-bursts is the standard tool in the redistricting-statistics literature for exploring biased-but-legal maps: it runs short MCMC chains (the "bursts") with the best-scoring map from each burst seeding the next, producing a hill-climb through the constraint-legal-map space toward an explicitly-defined objective.

Procedure. 40,000 ReCom steps, run as 800 short bursts of 50 steps. Within a burst every proposal is accepted; each burst restarts from the map with the most UCP seats@50/50 seen in the burst before (or from that burst's start, if nothing beat it). Same substrate as the Run #4–6 ensemble (4,765-VA 2023 votes, ±25 % population deviation, contiguity). Explicit objective: **maximise UCP seats@50/50**. Implementation at `analysis/scripts/targeted_gerrymander_burst.py`. Full run log at `archive/provisional_geometries/dpg/logs/v0_1_targeted_burst.log`.

Result. After 40,000 hill-climbing steps, the best map produced gave UCP **52.87 %** of seats at 50/50 votes — **within rounding of the minority map's 52.8 %**. The non-neutral procedure reaches the minority's range. The neutral procedure across 2,000,000 draws does not.

What this was read to confirm (superseded). The DPG-era reading below does not hold on official geometry: there the minority's 46 of 89 (51.69%) sits just below the neutral ensemble's maximum of 45 of 87 (51.72%), and 69 neutral plans exceed it (canonical

paragraph at the end of this subsection). The DPG-era reading was that the Run #6 converged-ceiling finding plus the Cannon et al. short-bursts result jointly demonstrated:

- **DPG-era: neutral procedures did not produce the minority's seats@50/50 reading.** 2,000,000 ReCom draws under EBCA constraints, ceiling at 51.72 %, zero draws at 52 % or above.
- **Non-neutral procedures can.** A partisan optimiser using short-bursts hill-climbing under the same constraints reaches 52.87 % in 40,000 steps.
- **The minority sits in the non-neutral procedure's reachable space, not the neutral procedure's.** Whether the minority commissioners used a partisan optimiser is not observable from public data — intent cannot be read off a map. What is observable is the minority map's seats@50/50 reading is one a partisan optimiser would produce and one a neutral procedure does not produce, under identical statutory constraints applied to identical Alberta geometry.

Why this matters for the §6.2 "out-of-distribution" framing. A reviewer could object — "out-of-distribution" is meaningless without specifying *which* distribution. The Cannon et al. result specifies it precisely: the minority map sits inside the distribution a non-neutral procedure produces (reachable via 40,000 hill-climbing steps) and outside the distribution a neutral procedure produces (unreachable across 2,000,000 random draws). The DPG-era framing was therefore: *the minority map is the kind of map a non-neutral procedure produces. It is not the kind of map a neutral procedure produces.* On official geometry that framing does not hold for seats@50/50, where a few neutral plans reach and exceed the minority; the canonical ensemble places the minority in the extreme tail (p99.99), not beyond the neutral range.

What this does not show. The short-bursts result does not show the minority commissioners used a partisan optimiser. It shows only — *if* one had been used, the minority's seats@50/50 reading is in the range the procedure would produce. The audit's restraint on intent is unchanged: intent is not observable from boundary geometry. The procedural-class mapping (neutral vs non-neutral) is.

Outputs: `analysis/scripts/targeted_gerrymander_burst.py` (short-bursts implementation), `data/targeted_burst_best.json` (best map's per-ED seat count and metadata), `data/targeted_burst_trace.csv` (per-step hill-climbing trace), `archive/provisional_geometries/dpg/logs/v0_1_targeted_burst.log` (full run log).

Canonical-substrate confirmation (2026-06-13; `findings/burst_pathways_canonical.md`). Both burst experiments were re-run on the official Elections Alberta canonical shapefiles. The targeted hill-climb (`targeted_gerrymander_burst.py`, 800 bursts × 50 steps = 40,000 steps, seed 137) reproduces the **52.87 %** figure exactly. That is a replay, not a check on substrate: the hill-climb reads only the voting-area graph, never the commission shapefiles, so with the same seed and input it returns the same map (`data/targeted_burst_best.json` matches the April output `data/outputs/mcmc/targeted_burst_best.json` to the last digit, apart from the declination sign fix and the recorded run time). 52.87 % (46 of 87) is the best this one

seeded run found, first reached at burst 233 of 800 (`data/targeted_burst_trace.csv`); nothing shows it is a maximum. The neutral short-bursts experiment (`simulation_short_bursts.py`, 500 independent 10-step ReCom walks from a single tight 87-district seed, not the 2019 map) places the minority map more extreme than *every one* of the 500 neutral walks on all four partisan metrics (efficiency gap, mean-median, declination, seats@50/50), with a neutral seats@50/50 ceiling of 0.4713 — well below the minority's 0.5169. The envelope is narrow: the 2019 enacted map also lies beyond every walk on declination, and at p98.6 on mean-median and p95.6 on efficiency gap, so lying outside it does not by itself set the minority apart. The majority map, by contrast, falls inside the neutral burst envelope (seats@50/50 burst-rank p88, efficiency gap p9.6, mean-median p0.2). The DPG-era ceiling comparison above does not carry over. On canonical geometry the minority has 46 of 89 UCP seats at 50/50 (51.69%). That is just below the 87-district ensemble's maximum of 45 of 87 (51.72%), which 69 of the 1,010,000 canonical plans reach. The hill-climb's best map has 46 of 87 (52.87%). The two counts of 46 sit on different denominators, so they are not compared directly. The canonical 1,010,000-plan ensemble (§5.4.9) places the minority's seats@50/50 at p99.99.

5.4.9 Canonical ensemble — official Elections Alberta shapefiles (1,010,000-plan, 4 chains × 252,500 steps; first completed 2026-05-12, rerun clean 2026-07-12)

This is the authoritative MCMC run. The §4.1.4 sunset clause bound the audit to re-run the ensemble against official shapefiles within two weeks of release. Official shapefiles were received 2026-05-06. This run supersedes all DPG-substrate runs (§5.4.1–§5.4.8) for the purpose of final percentile placements and the §6.2 verdict.

Substrate. The neutral plans are 87-district ReCom partitions of the 4,765 voting areas. Each chain starts from a fresh 87-part `recursive_tree_part` seed, because the 2019 map breaks ±25% on 2021 population (7 of its 87 districts). The 2019 map supplies only the district count. The official Elections Alberta files `ea_majority_2026_eds.gpkg` and `ea_minority_2026_eds.gpkg` (EPSG:3400, 89 EDs each) are used only to score the two commission maps. Vote substrate: same 4,765-VA 2023 votes and 2021 DA-weighted population as prior runs. Base seed: `get_canonical_seed("mcmc_ensemble_250k") = 1432864451` (drand round 5,500,000, public since October 2025, with the salt fixed in code on 2026-04-27 per the git record; corrected 2026-07-13 — the salt was previously mis-cited as "lunty-bootstrap" and the round as 5,800,000; the seed value 1432864451 was always correct and independently reproduces exactly from `get_canonical_seed("mcmc_ensemble_250k")` under the committed round 5,500,000). **Authoritative ensemble: 1,010,000-step run (4 chains × 252,500 steps; first completed 2026-05-12, discarded after the C9 defect and rerun clean 2026-07-12, C10).** The 250k run achieved partisan-metric n_eff 379–452 — sufficient for reliable percentile estimation through p99.9, but below the ~1,000–2,000 publication-grade threshold for individual tail claims at extreme percentiles. The 1,010,000-plan extension was run against the same seed

and shapefiles to achieve publication-grade ESS. It produced n_eff 1,413–1,522 (partisan metrics) and 2,772–5,654 (population MedAD and Reock proxy). Integrated autocorrelation time τ: 663–715 (partisan metrics), 179–364 (population/compactness). Convergence: rho_lag1 = 0.967–0.992. This exceeds the publication-grade threshold. The ESS caveat from the 250k run is resolved.

Per-chain ESS (T1.12 closed 2026-06-12 per T1.7 R2 Ref #2 D5). τ computed per chain (n=252,500 each) with the pipeline's estimator, `autocorrelation_ess` in `analysis/scripts/mcmc_ensemble.py`, which sums autocorrelations up to the first non-positive lag with a lag cap of 2,000 (the audit calls it Geyer's initial positive sequence), on the clean rerun chains in `data/simulation_checkpoints_canonical/`:

CHAIN	EG ESS	MM ESS	Δ ESS	S50 ESS	MIN
0	452	352	454	314	314
1	376	377	358	330	330
2	415	386	454	382	382
3	313	355	301	433	301

Summed across chains: ~1,556 / 1,470 / 1,567 / 1,459. These sums do not match the pooled n_eff cited above (1,522 / 1,448 / 1,513 / 1,413; C35), which is computed on the pooled chains; the pooled figures are the ones used. Largest per-chain τ ≈ 839 (chain 3 declination); a 5τ ≈ 4,200-sample burn-in per chain (~1.7% of the total) was investigated as a post-processing check; truncating those samples shifted no published percentile by more than 0.08 pp, and no minority placement by more than 0.05 pp. The headline percentiles are therefore robust to burn-in.

Chain-history note: an initial 50k run (2026-05-06, 2 chains) was superseded by the 4-chain 250k run. Chain1 experienced a sampler hang at chunk 12/50 during the 1,010,000-plan extension (documented 2026-05-11, commit 70e2695). The hang resolved and chain1 completed to 252,500 steps. The resume-path corruption risk T1.7 R1 Ref #2 D4 flagged (re-seeding with identical chain_seed on resume → step-0 replay) did fire once in that run: chain 1 rows 45,000–62,499 duplicate rows 25,000–42,499 (C9). The ensemble was discarded and rerun clean on 2026-07-12 after the fix (C10). All percentile placements below derive from the clean 4-chain 1,010,000-step rerun.

Constraint note — s.15(2) rural-protection disabled: The canonical ReCom run disables the s.15(2) rural-protection freeze (code: `analysis/scripts/mcmc_ensemble.py`, the s15(2) freeze note and `alberta_statutory_population_constraint`). The direction of the resulting bias is unknown. Without s.15(2), and with a ±12.5% proposal band, the ensemble produces *fewer* small rural districts than the Act allows, not more, so the earlier reading of the percentiles as conservative lower bounds does not follow. The decision is documented in hypothesis tracker entry H6. A constraint-enforcing run that freezes the s.15(2) districts was completed on 2026-06-13, at 100,000 steps for each of two seeds (§5.4.1), and later at 1,000,000 steps for each seed. On its 89-district plans the minority's mean-median, declination and seats@50/50 tails hold, at p98.3 or higher (the lowest is declination on the minority-seeded 1,000,000-step run, p98.35): further out under the majority seed, slightly in under the minority seed. Its efficiency gap is mixed (p94.17–p97.24).

Proposal-epsilon robustness (T1.11, *completed* 2026-06-13; *`findings/eps_full_robustness.md`*): The canonical proposal balances each ReCom bipartition to within ±12.5% (half the ±25% statutory band). Regenerating the full 1,010,000-plan ensemble at the full ±25% proposal band — same base seed, only the proposal epsilon changed — leaves every partisan-fairness percentile essentially unchanged: minority efficiency gap p94.39→p94.38, mean-median p99.98→p99.96, declination p98.79→p98.74, seats@50/50 p99.99→p99.97 (all shifts < 0.05 pp; the efficiency-gap and seats@50/50 ensemble bands are identical to two decimals; these baselines are from the first canonical run, before the 2026-07-12 rerun, which gives p94.54 and p99.97 for the first two). The partisan headline is invariant to the proposal-balance tolerance. The population placements do depend on the band. Full-band neutral plans are far more unequal than either commission map (ensemble median population MedAD ≈ 6,400, against the commission maps' 2,827 / 3,938). Against them the majority's MedAD sits at p0.0 and the minority's at p0.013 (135 of 1,010,000 plans are more equal), so both maps are more equal than almost every full-band plan. The full band was not adopted as canonical because its typical plan is more unequal than either commission map, which makes it a poor baseline for the population-equality test. The half-band ensemble is retained, and the full-band run is preserved as a robustness artifact (`run_id="eps_full"`). Every population MedAD placement in this section is therefore conditional on the ±12.5% proposal band. The statute-band set (set B of Amendment 5, Part 14: ±25% proposal band, size-matched 89- and 91-district plans) will test it again, and population measures in that set are read against the wider baseline.

Size-matched sets (*Amendment 5, Parts 14–17*; *`findings/pre_registration_amendment_log.md`*). Every canonical plan has 87 districts. The 2019 map is therefore the same-size comparison, and both 89-district commission maps are compared across sizes. The scoring spec's comparison against the 87-district plans stays the registered headline. Amendment 5, Part 14 adds neutral-map sets with the same number of districts as the map scored: 91 for the November map, 89 for the commission maps. Set A runs the canonical harness unchanged, with its ±12.5% proposal band. Sets B–D add three more. The statute-band set uses a ±25% proposal band. The municipality-aware set adds a soft weight on 2021 census subdivisions; Amendment 5, Part 14 fixes the weight at 0.5, and the set is a sensitivity reading, not a test. The s.15(2) set lets up to four districts fall as far as 50% below average when each meets three of the five s.15(2) criteria; Amendment 5, Part 15 specifies how each criterion is computed. Each set is reported beside the headline with its label, and none replaces it. A size-matched result is final only when its measure's effective sample size, pooled over chains, is at least 400 (Amendment 5, Part 16). Below that it is reported as provisional, with its n_eff. The first entry for these sets (2026-10-29) marked its 89-district runs for the commission maps as exploratory (not carried into Amendment 5). No result from these sets is reported here yet.

Per-metric percentile placements (canonical, authoritative):

MAP	METRIC	REAL-MAP VALUE	CANONICAL PERCENTILE (1,010,000 PLANS)	VS 250K RUN
2026 minority	**seats@50/50**	**0.5169**	**99.99 ⚠ flag reinstated** (n_eff=1,413 at 1,010,000 plans)	was p>99.9 empirical, retracted on ESS grounds at 250k
2026 minority	**mean-median**	**+0.0104**	**99.97 ⚠**	was 99.985, unchanged
2026 minority	**declination**	**+0.0770**	**98.79 ⚠**	sign corrected 2026-06-12, recorded in Amendment 5, Part 9 (was −0.0770 / p1.21 under the pre-Warrington implementation)
2026 minority	efficiency gap	+0.0402	94.54	was 94.2 — below p95, flag remains withdrawn
2026 minority	**population MedAD**	**3,938**	**99.1 ⚠** (±12.5% proposal band only; p0.013 under the ±25% statute band)	was 98.7, unchanged
2026 majority	mean-median	−0.0362	0.99 ⚠	NDP-tail outlier (partial-attribution basis; shifts to p5.74 under full-attribution variant — within null but NDP-favourable direction unchanged; no effect on any minority-map headline)
2026 majority	seats@50/50	0.4607	78.54 (upper edge of the 40/87 block)	was 78.6
2026 majority	efficiency gap	+0.0010	16.52	was 15.0
2026 majority	declination	−0.0267	21.85	sign corrected per Amendment 5, Part 9 (was +0.0267 / p79.6)
2026 majority	population MedAD	2,827	15.87 (±12.5% proposal band; p0.0 under the ±25% statute band)	was 15.6
2026 minority	Reock proxy median	0.579	100.0	unchanged
2026 majority	Reock proxy median	0.568	100.0	unchanged
2026 minority	Reock pct<0.30	1.1 %	0.09	was 0.08, unchanged
2026 majority	Reock pct<0.30	2.2 %	0.79	was 0.84, unchanged
2019 enacted	efficiency gap	+0.0241	69.46	baseline
2019 enacted	mean-median	−0.0077	91.81	was 92.1
2019 enacted	declination	+0.0451	91.33	sign corrected per Amendment 5, Part 9 (was −0.0451 / p8.95)

MAP	METRIC	REAL-MAP VALUE	CANONICAL PERCENTILE (1,010,000 PLANS)	VS 250K RUN
2019 enacted	seats@50/50	0.4598	78.54 (registered); 65.36 (tie-tolerant)	was 78.6

Source: `data/outputs/simulated_ensemble_raw_samples_canonical.csv` (1,010,000 steps, 4 chains × 252,500, seed 1432864451). 250k-run values shown in rightmost column for traceability. 2019 baseline rows added from `data/outputs/score_2019_baseline.json`. Population MedAD and Reock were not placed for 2019. Size is not the reason: the 2019 map has the same 87 districts as the plans. On 2021 population, 7 of its 87 districts fall outside ±25%, so the map lies outside the space the ensemble samples. Scored anyway, its MedAD is 3,085 (6.3% of quota), at p41.1. The 2026 MedAD and Reock rows are cross-size: they compare 89-district maps with 87-district plans. For MedAD, see the cross-size note under "Population MedAD" below. Seats@50/50 takes only values k/87 in the plans. The registered `pct_rank` counts ties by exact equality, and the 2019 map's 40/87 differs from the plans' 40/87 in the last floating-point digit, so the 266,278 plans at 40/87 all count as below it. Counting them as ties puts the 2019 map at p65.36; the registered value is p78.54. The majority's 41/89 falls between 40/87 and 41/87, so its p78.54 is the share of plans with 40 or fewer UCP seats: the upper edge of the 40/87 block. On the 89-district constrained nulls of §5.4.1 the majority sits at p51–p57.

Partisan metrics — 1,010,000-plan canonical (declination sign correction of Amendment 5, Part 9 applied 2026-06-12). The 1,010,000-plan run (4 chains × 252,500 steps, same seed and official EA geometry) achieves publication-grade ESS (n_eff 1,413–1,522) and resolves the ESS caveats from the 250k run. Three of four partisan metrics carry individual outlier flags on the minority map: mean-median at p99.97 (UCP-favoured tail), **declination at p98.79 (UCP-favoured tail; sign correction per Amendment 5, Part 9 — earlier drafts said p1.21 NDP-tail under the swapped-operand implementation)**, and seats@50/50 at p99.99 (the individual flag retracted at 250k on ESS grounds is reinstated at n_eff=1,413). Efficiency gap at p94.54 remains below p95. The EG outlier flag remains withdrawn. Population MedAD at p99.1 would add a fourth flag (exploratory Lane-1 channel), but only under the canonical ±12.5% proposal band. Under the ±25% statute band the minority sits at p0.013, more equal than almost every neutral plan, so this flag is conditional until the statute-band set (set B, Amendment 5, Part 14) reports. The minority's four-metric pattern: MM, declination, and seats@50/50 all in the UCP-favoured tail (three tail flags); EG directionally aligned but sub-threshold. The "asymmetric-packing" signature reading in earlier drafts of §5.2.4 was built on the swapped declination sign and is restated under the corrected sign in the acknowledgment paragraph there on the sign correction (Amendment 5, Part 9).

Majority mean-median: unexpected NDP-tail outlier. The majority map's mean-median of −0.0362 places at p0.99 (canonical 1,010,000-plan CSV, rerun 2026-07-12: 0.991188th percentile) — more NDP-skewed than 99.01% of neutral plans. The ensemble p5 is −0.0311. The majority map sits below the floor. Mean-median is mean(NDP district share) − median(NDP district share). A negative value means the mean is pulled down by a cluster of low-NDP districts. The majority's NDP district-share distribution has a pronounced left tail: numerous districts in the 15–30% NDP range drag the mean roughly 3.6 pp below the median.

Mechanism — Alberta settlement geography interacting with the ReCom-typical null. The majority map preserves a cohort of rural districts in the 15–30% NDP range, a pattern that is a geographic consequence of Alberta's settlement structure: dispersed low-density communities whose populations fall naturally into low-NDP ridings under any contiguous,

community-respecting draw. ReCom-typical plans are not constrained to maintain community integrity or municipal coherence, so they can merge, dissolve, or fragment these rural blocks in ways both real commission maps cannot. The ReCom-typical ensemble therefore contains many plans that dilute or reconfigure the low-NDP rural cluster, producing mean-median values closer to zero. On this reading the majority's NDP district-share distribution lands in the extreme left tail of a distribution generated by plans operating under fewer geographic constraints, because the ReCom null does not replicate the geographic discipline both real maps follow. The explanation is possible but untested, and it would apply equally to the minority's tails.

Severity-audit disclosure (T1.17 closed 2026-06-12 per T1.7 R1 Ref #16 D25; p0.85 error corrected 2026-06-14 per T1.7 R2 S24; p0.924 superseded 2026-07-12 by the clean ensemble rerun — p0.99 is the current canonical value). The geographic-null explanation above absorbs the majority's MM outlier (p0.99 per canonical `simulated_ensemble_percentiles_canonical.csv`, rerun 2026-07-12; the 250k run gave p0.85 and the since-superseded chain-1-duplicated 1,010,000-plan ensemble gave p0.924 — see DOCUMENTED CORRECTIONS C10) and the Reock / CSD-anchoring p100 placements on both maps. The same explanation applies symmetrically: the ReCom-typical null under-constrains all three real maps on municipal coherence, not just the majority on mean-median. Mayo's severity discipline (Mayo 2018, SIST Excursion 2) requires any null-mismatch correction be applied consistently across maps and metrics — not selectively where the correction weakens the audit's preferred conclusion. The audit's response: **rename the null "ReCom-typical plan" everywhere in the §6.2 verdict text** rather than "neutral commission drawing," because the actual ensemble samples ReCom-typical plans, not constraint-enforcing-commission-typical plans. The minority's MM (p99.97), declination (p98.79), and s50 (p99.99) tails are also measured against this unconstrained null; if the constraint-enforcing ensemble (T1.4) discounts those tails, it does so by the same factor it discounts the majority's MM outlier. The constraint-enforcing ensemble has since run (C24; §5.4.1): the minority's mean-median, declination and seats@50/50 tails stay at p98.3 or above under both seeds (further out under the majority seed, slightly in under the minority seed), and its EG is mixed (p94.17–p97.24). The audit's headline reads under the "ReCom-typical" framing and treats all tail flags as outliers relative to the *unconstrained sampling distribution* — not relative to the legal map space. The direction of the bias that framing introduces is unknown, so the headline $p \approx 1.76 \times 10^{-6}$ is not described as conservative.

Why the DPG runs did not show this. Earlier runs against Derived Provisional Geometries (DPGs) resolved VA-to-ED assignments using the audit's reconstructed boundary polygons. Official EA shapefiles resolve rural boundary ambiguities differently: some Voting Areas near rural–peri-urban fringe lines shift between EDs compared to the DPG approximations. These boundary-line differences in low-NDP rural districts are small in vote-count terms but sufficient to extend the left tail of the majority's NDP distribution past the ensemble p5. The official-geometry run is the first run capable of detecting this. The DPG runs did not have the spatial precision to surface it.

What this finding does not mean. The majority map is within the neutral null on every other metric: Efficiency Gap p16.5, declination p21.85, seats@50/50 p78.54, population MedAD p15.9 (±12.5% proposal band), Mahalanobis joint-tail p=0.102 (corrected 2026-07-08: previously stated Efficiency Gap p15.0, declination p80.6, seats@50/50 p78.6; the canonical values in `data/outputs/simulated_ensemble_percentiles_canonical.csv` were then p15.469, p20.378, and p77.81 respectively — since further updated by the 2026-07-12 clean ensemble rerun (DOCUMENTED CORRECTIONS C10) to p16.517, p21.849, and p78.538. The declination correction is directional, not a rounding fix: the majority's declination of −0.0267 sits at the 21.85th percentile, on the NDP-favoured side of the neutral distribution — not the 80th-percentile UCP-favoured side the earlier figure implied. The "within the neutral null" claim itself still holds). A single-metric NDP-tail outlier — mean-median only — accompanied by all other metrics within null may reflect Alberta's rural settlement geography interacting with the ReCom-typical null; that is untested, and the same explanation would be equally open to the minority. This outlier does not reverse the minority-majority asymmetry direction. The minority's MM is +0.0104 (UCP-tail, p99.97). The majority's is −0.0362 (NDP-tail, p0.99). Both sit outside the ReCom-typical distribution but in structurally opposite directions. The majority's MM outlier is reported as required by pre-registration. It does not support or undermine the minority-focused findings.

Population MedAD (new channel). This channel uses the median absolute deviation from the median district (MedAD), on 2021 census population overlaid on voting areas. That is a different statistic and a different base from the 48% headline in §5.1.1, which is the mean absolute deviation on the commission's July 2024 tables. Under the canonical ±12.5% proposal band, the minority map's MedAD of 3,938 persons places at p99.1: more unequal than 99.1% of neutral plans. Ensemble median: 3,161. The majority's MedAD of 2,827 places at p15.9, within the null. Under the ±25% statute band (`findings/eps_full_robustness.md`), the same values place at p0.013 (minority) and p0.0 (majority). So the channel points the same way as the Lane-1 partisan signals only under the canonical band. Under the statute band both maps sit in the more-equal tail, and the channel shows no unusual inequality on either map. The statute-band set (set B, Amendment 5, Part 14) will report it on size-matched plans.

Cross-size note. The commission maps have 89 districts and the canonical plans have 87, so the real maps' quota (47,894) is smaller than the plans' (48,995). Measured as a share of each map's own quota, the canonical-band placements are p21.0 (majority) and p99.6 (minority). The raw comparison therefore understates both maps' percentiles, by about 5 points for the majority and under 1 point for the minority. The statute-band placements stay below p0.1.

Reock proxy (null finding — reported as required by pre-registration). Both real maps score ABOVE the neutral ensemble on Reock median compactness (both at p100), and BELOW it on fraction of non-compact EDs. This is the expected result for commission maps following community-of-interest and municipal boundaries: such maps are systematically more compact than unconstrained random plans. The Reock channel does not provide additional

evidence against the minority map. The minority's pre-reported "2.58× Reock asymmetry" over the majority (comparing pct<0.30 across the two maps) was computed on the v0_9 topological substrate (derived shapefiles) and does not hold under canonical EA geometry: under official Elections Alberta shapefiles (received 2026-05-06), the between-map direction reversed — minority 4/89 = 4.5% below threshold vs majority 6/89 = 6.7% on the smallest-enclosing-circle Reock (see `findings/reock_verdict.md`); the ensemble's Reock proxy in the table above gives 1.1 % and 2.2 % (1 and 2 of 89), the same direction. The 2.58× ratio does not hold; see DOCUMENTED CORRECTIONS. Within the neutral null, both maps remain in the extreme-compact tail (both at p100 median Reock); neither map shows a between-map compactness asymmetry on canonical geometry.

CSD anchoring departure — MCMC edge-crossing test (OSF s58a6, dedicated ensemble, completed 2026-05-12). The municipal-anchoring-departure channel registered in OSF s58a6 but omitted from the Section C run was executed via a dedicated ensemble (`mcmc_anchoring_ensemble.py`; seed 80780579, claimed derivation: drand round 6099592, salt `"alberta-audit-anchoring-ensemble"`). **Seed derivation.** OSF s58a6 registers the derivation formula (`preregistration/seed_robustness_rerun.md`: the first eight hex digits of the SHA-256 of "salt:randomness"). Applied to drand round 6,099,592, whose randomness is archived there, with this script's salt it gives 80,780,579, the committed value. `analysis/scripts/drand_seed.py` uses a different formula, written for round 5,500,000, and does not reproduce it. The salt is recorded in `mcmc_anchoring_ensemble.py`, committed before the results (`49aee7b3` at 19:34 and `ea25e23f` at 21:05 on 2026-05-12), not in the registration. Metric: the fraction of cut edges in a neutral plan crossing a Statistics Canada Census Subdivision boundary. A cut edge connects two adjacent Voting Areas assigned to different Electoral Divisions. A CSD-crossing cut edge connects VAs in different CSDs. A higher fraction indicates district boundaries align with CSD divisions.

Two chains × 5,000 steps = 10,000 neutral plans. Ensemble: median = 17.82%, p5 = 16.73%, p95 = 18.97%. (2,065 of 13,385 VA adjacency edges cross a CSD boundary; all 4,765 VAs received a CSD assignment via centroid spatial join.)

Results: Majority 2026 — 37.63%, p100.00 (outlier, above p95 threshold). Minority 2026 — 29.75%, p100.00 (outlier, above p95 threshold).

Both real maps exceed all 10,000 neutral plans on this metric. This is expected for commission maps operating under municipal-boundary conventions: random ReCom plans face no such constraint. The **pre-registered direction is not confirmed**: the registration predicted the minority map would score below the ensemble median. The minority map is at p100, above all neutral plans. **This is a null finding on the "anomalous unanchoring" hypothesis.** The majority is more CSD-anchored than the minority (37.63% vs 29.75%), consistent with the direction noted in §5.8.5, but both maps sit in the anomalously high tail. This channel does not add to the joint headline: the anomaly direction is "more anchored than random," not "less anchored than random." Outputs:

`data/outputs/csd_anchoring_ensemble.csv`, `data/outputs/csd_anchoring_results.json`.

Independent seed check (Section C, seed 3562959107, 100k plans, completed 2026-05-12). A separate 100k-plan ReCom run using the pre-registered Section C seed (OSF s58a6; `analysis/methodology/robustness_rerun_seed_commitment.md`) replicates the population MedAD and Reock placements under the same ±12.5% proposal band. Key comparisons: minority population MedAD p99.26 (Section C) vs p99.1 (canonical 1,010,000-plan). This is a seed check, not a band check; the statute-band placement is above. Both Reock channels confirm the null finding at p100 median compactness and low-elongation direction for both maps. Partisan metric placements are consistent within expected sampling variation (e.g. minority EG p93.93 vs p94.54. Minority seats@50/50 p100.0 vs p99.99). Municipal-anchoring-departure channel: not captured in the Section C run — executed separately via `mcmc_anchoring_ensemble.py` (see above). Section C output: `data/simulated_ensemble_raw_samples_section_c.csv`. That file holds two chains and stores each 5,000-plan chunk twice (200,000 rows for 100,000 plans); exact duplication leaves the percentiles unchanged, but its row count is not a plan count. The Section C seed, 3,562,959,107, is the rerun base seed OSF s58a6 registers (salt `alberta-audit-mcmc-rerun-base`, round 6,099,592, under the registered formula; `preregistration/seed_robustness_rerun.md`). `drand_seed.py` with the salt `mcmc_ensemble_section_c` does not reproduce it, because that is not how it was derived.

Mahalanobis joint-tail test. The four canonical metric scores jointly produce Mahalanobis D = 5.80 with p = 8.80×10^{-7} under the 1,010,000-plan canonical ensemble's covariance matrix. The majority's joint p = 0.102 (within null). Both joint p-values compare 89-district maps with 87-district plans. The minority's per-metric tails on mean-median, declination and seats@50/50 hold on the 89-district constrained nulls of §5.4.1, at p98.3 or higher. A size-matched D^2 will come from the 89-district chains of Amendment 5, Part 14, and will be reported once their pooled n_eff reaches 400 (see "Size-matched sets" above). Classification: **exploratory** (§4.3.3) — the ensemble seeds derive from a public drand round with salts fixed in code before shapefile receipt (dated by the git record), but neither this test nor its combination method was named in any OSF registration before execution. (Corrected 2026-07-08: an earlier draft of this paragraph stated "Pre-registered at OSF 6pt83"; 6pt83 is the Ch2 SZAT registration and does not cover this test.) *Empirical verification scan (added 2026-07-08; dependence-honesty correction 2026-07-11; rerun 2026-07-12).* A direct scan of all 1,010,000 ensemble plans (`analysis/scripts/verify_joint_empirical_bound.py`; output `findings/joint_empirical_bound_verification.json`) finds an ensemble maximum D^2 of 28.43 — no sampled plan reaches the minority's D^2 = 33.64. An earlier version of this note (2026-07-08) described the resulting (b+1)/(B+1) figure of $p \le 9.90\times10^{-7}$ as a "distribution-free" bound *tighter* than the parametric headline. **That description was wrong**: (b+1)/(B+1) assumes the ensemble samples are exchangeable with the observed map, and MCMC samples are not — the D^2 series' measured integrated autocorrelation time is $\tau \approx 214$–251

per chain, so the 1,010,000-row scan carries only n_eff ≈ 4,372 effective samples (pooled, 4 chains), and zero exceedances honestly supports (rule of three) an empirical upper bound of 3/n_eff ≈ 6.9×10^{-4} — nearly three orders of magnitude weaker than the naive figure. The scan's two Gaussianity-free contributions stand: no sampled plan reaches the minority's joint profile, and in the region the ensemble can actually observe the parametric model tracks the empirical tail closely (majority: parametric 0.1017 vs empirical 0.1011; 2019 enacted: 0.0105 vs 0.0122), supporting the $\chi^2(4)$ extrapolation. The sub-10^{-6} headline ($p = 8.80\times10^{-7}$, parametric and unadjusted; the n_eff-adjusted parametric value is 1.11×10^{-6}) therefore rests on the parametric model — validated where checkable, extrapolated beyond it — and is stated as such, not as an assumption-free empirical fact. *Methodological note on autocorrelation:* The Mahalanobis degrees of freedom uses 4 (number of metrics) and does not formally discount for autocorrelation within the MCMC chain. Effective sample sizes from the 1,010,000-plan canonical run: EG n_eff=1,522, MM n_eff=1,448, Decl n_eff=1,513, seats@50/50 n_eff=1,413 (integrated autocorrelation times τ=663–715); Hotelling T^2 n_eff correction yields n_eff=1,413 conservative lower bound. At these ESS levels the publication-grade threshold (~1,000–2,000) is met; the ESS caveat is resolved. The $p = 8.80 \times 10^{-7}$ value reflects the 1,010,000-plan covariance matrix. n_eff-adjusted (Hotelling T^2): $p = 1.11 \times 10^{-6}$ — both are far below any conventional threshold. The difference reflects the more conservative n_eff estimate under the Hotelling correction.

Inter-map comparison permutation test (Ch1-COMP). Pre-registered at OSF yvc7g (drand seed 1823538405, salt "ch1-comp"). H_0: the minority-majority partisan-metric gap is no larger than the one for randomly drawn neutral-plan pairs. Results reported regardless of direction per pre-commitment.

Version A (EG-only, one-tailed; T1.6 rescore against canonical 1,010,000-plan ensemble landed 2026-06-12, supersedes 250k v0_9 result): observed minority–majority EG gap = +3.92 pp. Null SD = 2.17 pp; null 95th percentile = +3.54 pp; **p = 0.0348** against the canonical 1.01M ensemble (round-1 published p = 0.0303 against the 250k v0_9 ensemble; the canonical re-run shifts the percentile slightly but preserves significance at $\alpha = 0.05$).

Version B (Mahalanobis joint, one-tailed in distance; T1.6 canonical rescore 2026-06-12): observed inter-map distance **D = 7.20** against a null 95th percentile of 4.37; **p = 0.0002**. Post-correction (Amendment 5, Part 9), **4/4 metrics point minority more UCP-favorable** (EG +3.92 pp, mean-median +4.66 pp, seats@50/50 +5.62 pp, declination +10.37 pp Warrington UCP-favoured). Earlier drafts reported declination as reversing ("3/4 with declination opposing") — that was the swapped-operand artefact corrected on 2026-06-12 (Amendment 5, Part 9); under the corrected sign all four metrics agree on direction. Both versions significant; verdict: **SUPPORTED at classical threshold on both versions** under canonical 1.01M ensemble.

Contextual framing. The primary significance claim is each map's absolute position relative to the ensemble (minority $p = 8.80\times10^{-7}$; majority p = 0.102; corrected 2026-07-08: previously stated as 0.125 — the value in `findings/joint_outlier_score.json` for the old 250k-era run was joint_partisan_p = 0.09713; the canonical 1.01M-plan value is 0.1017). Ch1-

COMP tests a different question: do the two maps differ from each other more than randomly chosen neutral pairs? The answer is yes. This confirms the minority-majority asymmetry is not an artefact of both maps occupying similar extreme positions — they are separated by more than the typical inter-plan distance in partisan-metric space. Output: `findings/intermap_permutation_test_results.json`.

Joint statistic (revised 2026-06-10; recomputed 2026-07-12). The earlier Fisher combination applied to the two primary analytical channels (Channel 1 Mahalanobis p-value and Channel 2 SZAT permutation p-value) produced T = 39.87 / p ≈ 4.61×10^{-8} on the rerun ensemble — but Fisher's method assumes independence between the channels, and Ch1 and Ch2 are not independent (they share underlying 2023 vote-attribution data and overlap on the EG dimension). The audit's now-preferred joint statistic is the parametric Ch1 value doubled for two channels, **p ≈ 1.76×10^{-6} (≈ 1 in 568,000)**; the doubling is valid under arbitrary dependence between the channels, and its input is a model extrapolation past the sampled maximum (the sample alone supports p below about 6.9×10^{-4}). A dependence-aware Brown's-method scaling or Cauchy combination (Liu & Xie 2020) is left as future work. *Note on superseded calculation:* The Fisher-combined figure (as published on 2026-06-10, T = 39.03, p ≈ 6.87×10^{-8} on the chain-1-duplicated 1,010,000-plan run; T = 39.87, p ≈ 4.61×10^{-8} on the rerun) is documented as retired due to the channel-dependence violation; the current headline joint-probability is the Bonferroni bound at p ≈ 1.76×10^{-6}.

SZAT p-value history: A first draft of the registration reported p < 0.0001 from an additive-delta approximation of the bootstrap null. The registration (OSF 6pt83) specified a full map EG recompute per permutation, and the full-recompute run it reports gave p = 0.0044. After registration, a switch of VA file that changed 2 centroid assignments moved the value to p = 0.0024 (§5.2.10, 2026-05-10); that switch is the only cause of the 0.0044 → 0.0024 shift. The 0.0024 is the value once used in the retired Fisher combination. SZAT itself is retired under the block-permutation null (p ≈ 0.19).

SZAT substrate description correction (§5.2.10, 2026-05-12). A prior version of §5.2.10 (the "Post-registration substrate update" paragraph, committed ~2026-05-10) incorrectly described the definitive SZAT run as using a "full advance-vote substrate" in which advance-vote and special-ballot totals were apportioned to individual VAs proportionally by election-day share, increasing province-wide NDP two-party share from 42.60% to 44.66%. This description was false. Verification against both the current `szat.py` script and the git diff for commit `bd721d9` confirms: the script reads `va_ndp/va_ucp` columns (election-day only; two-party total ~896,644) throughout both the initial and definitive runs. The p change from 0.0044 to 0.0024 was caused by a VA file switch (`va_polygons_with_2023_votes.gpkg` → `va_polygons_with_full_2023_votes.gpkg`) changing 2 VA centroid assignments (2,108 → 2,110 swing zones due to minor geometric differences between the two files), not by any substrate change. The commit message "SZAT updated to full advance-vote substrate" (bd721d9) was itself incorrect. The pre-registration (OSF 6pt83) specified election-day votes. The actual execution used election-day votes. There was no post-registration substrate deviation. The pre-registered finding

(p=0.0024) is corrected to accurately describe election-day substrate. A genuine full-vote sensitivity (advance-ballot-apportioned `va_ucp_full/va_ndp_full` columns; ~1,544k two-party) was run on 2026-05-12 and reports p < 0.0001; see §5.2.10.

Implication for §6.2. The §6.2.5 DPG-era framing (minority s50 = 52.8%, above v0_8 ceiling 51.72%) is superseded. Under canonical geometry, the minority s50 = 0.5169, which exceeds nearly all plans in the 1,010,000-plan canonical ensemble (p99.99; 69 of 1,010,000 neutral plans exceed it, all at 45/87 = 51.72%). The "out-of-distribution" framing in §6.2.5 is superseded: on official geometry the minority is in the extreme tail (p99.99), below the ensemble's maximum, not beyond it. All four partisan metrics now align in direction, rather than seats@50/50 alone (three carry individual tail flags at ≥p95; EG at p94.54 is directionally aligned but sub-threshold). The §6.2.1 Effect Size table at the DPG numbers (48.31%, +2.21 pp) is superseded. The canonical minority s50 = 51.69% with the neutral ensemble distribution placing it at p99.99.

Outputs: `data/outputs/simulation_convergence_diagnostics_canonical.json`, `data/outputs/simulation_real_map_scores_canonical.json`, `findings/joint_outlier_score.json`.

Git history rewrite — commit hashes changed (2026-05-12). On 2026-05-12, `git filter-repo` was used to scrub personally identifiable information from all 392 commits. This rewrote every commit hash in the repository. No analytical outputs, data files, scripts, or report text were altered. The OSF registration s58a6 (robustness checks and pending channels) cites the git hash `72f7e01` as the committed state "before execution." The hash no longer exists in the repository. w2s8k, r3zm7, qsgy8 and 6pt83 all cite commit `d2aea42`, which the rewrite also orphaned. The authoritative registration evidence is the OSF timestamp record, which is unaffected by this rewrite. Reviewers who clone the repository after 2026-05-12 will see no gap in analysis continuity. The author's position is that the rewritten history is identical in all substantive respects to the original, but that cannot be checked from the rewritten repository: git dates, including the April 27 salt commit, are not third-party evidence.

5.4.10 2019 enacted baseline — measuring the void

The 2019 enacted map scored against the canonical 1,010,000-plan ensemble provides a third reference point: the pre-existing state from which both 2026 proposals were drawn. Comparing all three maps in the same metric space reveals the *direction of travel* — which proposal corrected the 2019 partisan structure and which amplified it.

Direction-of-travel table (canonical 1,010,000-plan ensemble, exploratory).

METRIC	2019 ENACTED	MAJORITY 2026	MINORITY 2026
Efficiency gap	+0.0241 (p69.5)	+0.0010 (p16.52)	+0.0402 (p94.54)

METRIC	2019 ENACTED	MAJORITY 2026	MINORITY 2026
Mean-median	−0.0077 (p91.81)	−0.0362 (p0.99)	+0.0104 (p99.97)
Declination	+0.0451 (p91.33)	−0.0267 (p21.85)	+0.0770 (p98.79)
Seats@50/50	0.4598 (p78.54; tie-tolerant p65.36)	0.4607 (p78.54)	0.5169 (p99.99)
Mahalanobis D^2 (joint)	13.16 (parametric p=0.0105; empirical 0.0122)	7.74 (p=0.102)	33.64 (parametric $p=8.80\times10^{-7}$)

Exploratory (not pre-registered). Source: `data/outputs/score_2019_baseline.json` (Mahalanobis), `data/outputs/simulated_ensemble_raw_samples_canonical.csv` (per-metric, 1,010,000-plan run). D^2 values computed from 1,010,000-plan covariance matrix; see `findings/joint_outlier_score.json`. Attribution note: all percentile values in this table use partial-coverage VA data (va_ndp; election-day only, ~50% of actual votes) — the canonical ensemble substrate. A full-vote ensemble cannot be built (Elections Alberta publishes no VA-level advance/special data; see §3.2), so the full-coverage check ranks full-coverage real-map values against this same election-day ensemble. On that basis the minority map's outlier direction persists on all four metrics, and the majority mean-median moves from p0.99 to p5.74 (direction unchanged). This establishes directional persistence under full-coverage real values — not a full-vote percentile or a re-derived joint p, which the data EA publishes do not permit. See `analysis/methodology/provenance/vote_attribution_provenance.md`.

Mahalanobis joint-tail finding. The 2019 enacted map is itself a mild joint-space outlier: D^2 = 13.16, parametric p = 0.0105; empirically, 1.22% of the 1,010,000-plan ensemble has higher D^2. The majority 2026 map reduces this distance to D^2 = 7.74 (p = 0.102) — well within the neutral null. The minority 2026 map amplifies it to D^2 = 33.64 ($p = 8.80\times10^{-7}$ under the 1,010,000-plan ensemble). The joint distance from 2019 to the neutral null is thus: majority *retreated toward neutral*, minority *advanced toward a more extreme position*. The 2019 baseline was not itself a clean neutral starting point. What the two groups of commissioners did with it differs fundamentally.

Metric-by-metric reading (sign correction of Amendment 5, Part 9 applied). Under the corrected Warrington convention, the 2019 map's declination is at p91.33 (mild UCP-side), Seats@50/50 at p78.54 as registered (p65.36 once ties are counted; see §5.4.9), and EG at p69.5 (near centre). Mean-median at p91.81 means 2019 was slightly less NDP-efficient in mean-median terms than most neutral maps — a mild UCP structural advantage. The majority 2026 moved declination toward NDP-side neutrality (2019 p91.33 → majority p21.85), left Seats@50/50 nearly unchanged (40 of 87 UCP seats at 50/50 → 41 of 89), and moved EG toward neutral (p69.5 → p16.52). The minority 2026 pushed declination further into the UCP-favoured tail (2019 p91.33 → minority p98.79), dramatically extended MM in the UCP direction (p91.81 → p99.97), and pushed Seats@50/50 into the far tail (40 of 87 → 46 of 89; p99.99). The minority's 51.69% sits just below the ensemble's maximum of 45 of 87 (51.72%). (*Percentiles corrected 2026-07-08 to the values in `data/outputs/simulated_ensemble_percentiles_canonical.csv`: 2019 seats@50/50 p77.81 not p78.6; 2019 mean-median p91.54 not p92.1; majority EG p15.47 not p15.0 — since further updated by the 2026-07-12 clean ensemble rerun, DOCUMENTED CORRECTIONS C10, to 2019 seats@50/50 p78.54, 2019 declination p91.33, majority EG p16.52, and majority seats@50/50 p78.54.*) Earlier drafts of this paragraph read the cross-map declination

movement under the swapped-operand sign — see Amendment 5, Part 9 in `findings/pre_registration_amendment_log.md` for the convention correction.

Population dispersion (cross-map comparison, exploratory). The figures on each map's own drawing base are not comparable. The 2019 map's mean absolute deviation on the 2017 EBC report (87 EDs, total 4,071,875, quota ≈ 46,803) is 2,886, or 6.2% of quota. The commission tables give the 2026 maps 3,180 and 4,707 (5.8% and 8.6% of 54,929) on a July 2024 base. The 2026 MedADs in §5.4.9 (2,827 and 3,938) are a different statistic on a third base. These figures should not be ranked against each other. On one base, the 2021 census overlaid on voting areas, the like-for-like figures are as follows. Mean absolute deviation from each map's own quota: 2019 map 9.7%, majority 10.1%, minority 10.2%. MedAD: 2019 map 3,085 (6.3% of its quota), majority 2,827 (5.9%), minority 3,938 (8.2%). On the mean the three maps are almost level. On MedAD the minority is the widest and the majority the tightest. Appendix C gives the full table and the cycle-lag caveat.

Cross-size declination caveat (T1.18 closed 2026-06-12 per T1.7 R1 Ref #5 D29). Every canonical plan has 87 districts, the 2019 map's count. The 2019 map is therefore the same-size comparison, and $\tilde{\delta}$ equals δ for it. Both 2026 maps have 89 districts, so their placements are cross-size. Warrington (2018) §6 gives $\tilde{\delta} = \delta \cdot \ln(n)/2$ for comparisons across sizes. Between n = 87 and n = 89 the factor differs by about 0.5% ($\ln(87)/\ln(89) = 0.9949$). Rescaling the 2026 maps' δ by $\ln(89)/\ln(87)$ moves the majority from p21.85 to p21.74 and the minority from p98.79 to p98.81. The audit cites raw δ throughout. This bound covers declination only. It does not cover seats@50/50, where the plans take values k/87 and the 2026 maps k/89, or population MedAD, where the quota depends on the number of districts. §5.4.9 treats both, and describes the size-matched sets of Amendment 5, Parts 14–17.

SZAT 2019 baseline (exploratory, not pre-registered). The SZAT of §5.2.10 tested whether the minority's specific boundary *choices* — the 2,110 VAs assigned differently between the two 2026 proposals — were partisan-neutral. The exploratory SZAT baseline applies the same logic to 2019→2026 movement: of the VAs each commission had to move from 2019 positions, did they move them in a partisan direction?

COMPARISON	SWING VAS	SZAT SCORE	BOOTSTRAP P (10K)
2019 enacted → majority 2026	2,042	−0.0231	0.309
2019 enacted → minority 2026	2,584	+0.0161	0.053

Exploratory. Seed: `get_canonical_seed("szat-2019-majority") / "szat-2019-minority")`. Source: `findings/szat_2019_baseline.json`.

The majority's boundary choices from 2019 produce a SZAT score of −0.023 with p = 0.31: statistically indistinguishable from random. The observed score falls within the bootstrap null 95% CI [−0.034, −0.006]. The EG shift from 2019 to majority is consistent with any neutral rearrangement of those swing zones. The minority's boundary choices produce a SZAT score of +0.016 with p = 0.053: marginally above the 5% threshold. The output file also reports a null 95% CI of [−0.017, +0.006], which the observed +0.016 lies above; that does not square with p = 0.053, so one of the two figures is wrong and the result should be read

as borderline. The minority's choices moved EG in the UCP-favoring direction. Note the null CI is near-symmetric for the minority (unlike the majority, where any random redistricting from 2019 tends to push EG negative), because the minority's non-swing VAs have a different partisan composition. These are exploratory findings, as is the §5.2.10 SZAT between the two 2026 proposals (registered after first results; retired under the block null).

5.5 Pre-registered checklist baseline scoring

The "what a gerrymander would look like" checklist pre-registered in `report_public.md` was applied to both 2026 commission maps as a calibration test before it is applied to the advisory panel's 91-seat map (delivered to the committee on October 22, 2026). The scorecard, from `findings/checklist_baseline_scoring.md` (that file's X2 row counts the shared-schools claims as contradicted and scores the minority's X2 as three triggered; the X2 row below follows §5.9.6):

SIGNAL CLASS	MAJORITY 2026	MINORITY 2026
Strong signals triggered (of 4 scorable; S3 and S5 deferred)	0	0 counting Airdrie's pieces by people (S1: two of three signatures; Airdrie is three pieces). 1 on the registered territory count (S1: three of three; Airdrie is four districts)
Weak signals triggered (of 2 scorable)	0	2 (W2 Calgary zone gap, W3 Nolan Hill-Cochrane retention)
Process signals triggered (of 5)	0	0
Rationale-against-data contradictions (X2)	0	0 (the two shared-schools contradictions once counted do not stand: R11 Red Deer-Sylvan Lake's "go to school" tie is partly supported, because Red Deer Catholic Regional serves both places, and R5 Calgary-Bow-Springbank's "educational institutions" was not tested against data that measures it; Cochrane commuter-tie partial; five population-math tests failed; §5.9.6)

*Under the checklist's stated honest-test threshold ("three signatures plus at least one new signature plus ensemble-outlier or public-support-inversion"), neither map qualifies as a sure-sign gerrymander. Counted by people, the minority falls one short of the signatures clause: this scorecard counts the pieces in the checklist's S1 Airdrie test ("a 4-way or greater Airdrie split") by people, borrowing the 2 % piece rule that Amendment 5, Part 17 sets for its town-split test (no amendment applies that rule to S1), and the minority's split is three pieces by people (four districts by territory), so it carries two of S1's three signatures. Counted by territory, as registered and as the scorecard stood when the specification was frozen, the minority's four Airdrie districts give it all three signatures and one strong signal; it still falls short of the sure-sign bar, because it adds no new signature. (These are the checklist's signatures, not the formal P/C/E signatures of §5.3, none of which is detected on the official maps: packing fails its margin test, and cracking and the engineered-boundary signature are not detected; §5.3.4.) It does, under the 1,010,000-plan canonical MCMC run reported in §5.4.9, meet the ensemble-outlier clause on three of four partisan metrics: Mean-Median at p99.97, **Declination at p98.79 (UCP-tail, post-correction; Amendment 5, Part 9)**, and Seats@50/50 at p99.99 (individual flag formally reinstated at 1,010,000-plan ESS). Efficiency Gap at p94.54 falls just below the p95 threshold and is not flagged (p94–p97 under the constrained runs). Population MedAD fires at p99.1 under the canonical ±12.5% proposal band only; under the ±25% statute band the minority sits at p0.013, in the more-equal tail. It does not introduce new formal signatures — the Lethbridge and Red Deer 4-way patterns in §5.6 are symmetric-test-derived cracking candidates held separately from the formal P/C/E signature set pending the C-criteria threshold run — and does not invert public support. The scorecard is internally consistent with the audit's existing qualitative conclusions — the minority is measurably UCP-favourable but does not cross the sure-sign bar. The scorecard's value going forward is twofold: it operationalises the pre-registered test for the November map, and it demonstrates the test distinguishes the two known maps in the expected direction before any new map is drawn.*

External registration. The November tests are in `preregistration/november_2026_scoring_spec.md` (June 2026, dated in this repository), which decides the verdict. The 17-test checklist registered on OSF (9wp5y, registered 2026-05-07) was scored on the panel's map on 2026-11-09, after its registered 72-hour window had closed (grid and its §5 result: `findings/checklist_9wp5y_panel_map.md`). OSF qsgy8 (registered 2026-05-06) registers four tripwires (MO #1–#4), reported beside the verdict. The November drand round is to be pinned at or after the map's release. The submission-ready checklist document is in `analysis/reports/pre_registration_draft.md`.

The 17 checklist tests (OSF 9wp5y), in optimal execution order. The tests are grouped by what data they require. Tests requiring nothing but public documents are scored first. The one test requiring shapefiles and compute time is scored last.

Group 1 — Process checks (answerable before map tabling, from public committee records):

- **P2 — Advisory panel transparency.** Tests whether the committee publicly names its advisory panel members and publishes terms of reference before or with map release. An anonymous advisory structure prevents public scrutiny of the qualifications or political alignment of the people who shaped the drawing.
- **P1 — Public hearings held.** Tests whether the committee held public hearings on a draft map before finalizing it. Public hearings are the standard mechanism by which affected communities can contest boundary choices before they are fixed.
- **P3 — Draft consultation window.** Tests whether a draft map was released for public comment with at least a 14-day window. A direct-to-final release eliminates the opportunity for community-specific objection before adoption.

Group 2 — Immediate post-release (no computation; ED names and release documents sufficient):

- **P5 — AI disclosure.** Tests whether the committee discloses all AI tools, prompts, model versions, and random seeds used in drafting, against the audit's published framework (`docs/ai_use_recommendations_for_committee.md`). Undisclosed AI involvement makes the derivation of the map unreproducible and unauditable.
- **S6 — Public-support inversion.** Tests whether the final map drops configurations with documented submission-archive support while keeping configurations with none. The archive's 1,252 machine-searchable submissions (of 1,345; §5.9.4) are already compiled; only the November map's configuration names are needed to score this test.
- **X1 — Chair Miller's four conditions** (scoring rule: Amendment 5, Part 13). Tests whether the November map meets the conditions of Chair Miller's Recommendation 5: (a) no change to any division in Airdrie or with territory south of Airdrie's southern boundary, except Drumheller-Stettler; (b) no change to any Edmonton division north of the North Saskatchewan River; (c) south-of-river Edmonton divisions returned to the interim-report map; and (d) the committee *considered* restoring a division mostly of Clearwater County and western Mountain View County with s.15(2) status, scored adopted /

considered with a stated reason / not shown. X1 is met only if (a)–(c) are met and (d) is adopted or considered with a stated reason; the strict reading of (d) is reported beside it. R5 binds no one in law, and Government Motion 37 lets the panel modify it, so X1 tests whether the committee delivered the proposal the government cited, not legal compliance.

Group 3 — Same-day structural checks (census and population data; no 2026 shapefiles required):

- **S1 — Three minority signatures.** Tests whether the November map carries the same three formal structural signatures as the minority proposal: a ≥10% Calgary zone-population gap, a 4-way or greater Airdrie split (registered wording; the baseline above also counts pieces by people, with a 2 % piece rule borrowed from Amendment 5, Part 17's town-split test, which no amendment applies to S1; `findings/checklist_baseline_scoring.md`), and an s.15(2) district anchored to ≥20% uninhabited protected land. Co-occurrence of all three defines the audit's gerrymander-signature criterion.
- **W2 — Calgary zone gap (weak signal).** Tests whether any Calgary zone partition shows a ≥5% mean-ED-population gap — the weak version of S1's 10% threshold. A result in the 5–10% band extends the packing inference to the Lunty map at reduced certainty.
- **W1 — Rural seat count.** Tests whether the committee added 2 rural seats relative to the 89-seat majority baseline without engineering. A plain rural addition consistent with the government's stated rationale is a pass; an engineered addition triggers S3.
- **S3 — Both rural additions engineered.** Tests whether both incremental rural seats invoke s.15(2) with boundaries enclosing ≥20% uninhabited protected land — the same pattern identified as anomalous in the minority's RMH-Banff Park extension. Scored after W1 confirms two rural additions were made.
- **S2 — Novel structural signatures.** Tests whether the November map introduces signatures absent from the minority: an Edmonton zone-packing gap ≥10%, a 4-way or greater city split in a third Alberta municipality, or an additional engineered s.15(2) boundary beyond any found in S1/S3. A positive result extends the structural finding beyond what the commission itself drew.
- **W3 — Nolan Hill-Cochrane retained.** Tests whether the committee keeps the minority's Calgary-Nolan Hill-Cochrane hybrid without stronger justification than the commuter-tie claim, which the CSD data only partly support: the largest flow stays within Cochrane, and Calgary is the largest out-of-town destination (`analysis/methodology/reference/cochrane_journey_to_work.md`). Retention with only the same weak rationale means the committee inherited a contested boundary without filing new evidence to defend it.

Group 4 — Requires committee per-ED rationale document (up to 24 hours after release):

- **X2 — Rationale-against-data contradictions.** Tests each of the committee's stated per-ED rationales against public datasets (Alberta Education school-division boundaries,

StatsCan journey-to-work table 98-10-0459, Alberta Treasury population estimates, 2021 census CSD populations). A rationale fires when directly falsified by the dataset it invokes; ≥3 contradictions elevate to a strong signal. This test would catch a shared-schools claim like those checked in two minority configurations (§5.9.6).

Group 5 — Vote reallocation (crosswalk computation; run in parallel with Group 4):

- **S4 — Efficiency gap ≥7%.** Tests whether the November map's efficiency gap, computed on 2023 provincial election votes reallocated to the new 91-seat boundaries via the audit's crosswalk, exceeds the 7% investigable-bias threshold (the figure entered US litigation through Jackman's expert analyses in *Whitford v. Gill*; §5.2.8). This is the Lane 1 partisan-bias magnitude check — the single most internationally comparable gerrymandering threshold.
- **X3 — 338Canada cross-validation.** Tests whether 338Canada's riding-level projection, reallocated to the November 91-seat boundaries via the audit's crosswalk, gives UCP ≥2 more seats than the majority 89-seat baseline (established at 67 UCP / 22 NDP in the April 2026 snapshot). Provides a poll-based projection independent of the 2023 vote baseline.

Group 6 — Post-adoption (may fall outside the 72-hour scoring window):

- **P4 — Adopted without amendment or dissent.** Tests whether the Legislature adopts the committee's map without amendment and without any published committee dissent. Unanimous unamended adoption eliminates the last procedural correction mechanism; dissent or amendment shows the process retained factual-check capacity.

Group 7 — Requires 2026 shapefiles and MCMC compute (48–72 hours; BLOCKED if no shapefiles released):

- **S5 — Ensemble outlier.** Tests whether the November map's UCP-favourability percentile falls in the top 5%. The registered reference is the fixed 1,010,000-plan canonical ensemble (GerryChain ReCom, published seed, 4 chains × 252,500 steps; the pre-registration minimum is 10,000), whose plans have 87 districts. That comparison stays the headline. Beside it, the map is scored against the size-matched 91-district sets of Amendment 5, Part 14 (§5.4.9). A size-matched result is final only when its pooled n_eff reaches 400 (Amendment 5, Part 16). This is the strongest single statistical test in the scorecard — the test placing the minority at p94–100 on all four partisan metrics — and requires official shapefiles possibly not released with the November map.

5.6 Symmetry-of-test-selection audit

The audit applies each analytical test identically to both 2026 maps (test-application symmetry, see §4.1.1). A separate discipline, *test-selection symmetry*, asks whether the tests themselves were designed around observed minority features rather than around structural features either map could exhibit. Earlier drafts attributed this discipline to Chen

and Rodden (2013) — corrected 2026-06-12 per T1.7 Referee #9; Chen-Rodden 2013 (8 QJPS 239) is about *geography-driven bias*, not about test-selection-design discipline. The actual discipline is closer to Best et al. (2018) on operationalization choices driving packing/cracking verdicts, and to the broader pre-registration literature (Nosek 2018) on hypothesis-generation prior to data inspection. To address this discipline, a counter-test was constructed (`analysis/scripts/majority_symmetry_counter_test.py`, 2026-04-22) generating symmetric hypothetical tests and applying them to both maps.

Equal-application disclosure — the minority's published criticism of the majority (added 2026-07-14). The audit's asymmetric evidence sources run in both directions, and both are recorded. Against the minority: the commission majority's four boundary objections and its "no public support" statements (final report pp. 59 and 62–63; §5.8.2; the audit confirmed three of the four boundary objections and found the public-support claim right for three of the five places it names and partly wrong for two, §5.9.4). Against the majority: the minority report charges the majority with "the Majority's inclination to delete or mangle rural electoral divisions and, in effect, reduce effective rural representation" (minority report, p. 356; see also p. 287: the minority "departed from the majority where we believe the legislative direction given to the Commission and the thoughtfulness of public submissions has not been given sufficient effect"). The minority's charge is partially operationalized by T3.2 (`preregistration/t3_2_majority_rural_isolation_design.md`, exploratory), which tested whether the majority's rural districts are engineered isolation corridors and returned the geographic null (H_0 supported). The charge's specific mechanism — elimination or amalgamation of rural divisions relative to 2019 — was counted per map the same day the charge was surfaced (`analysis/scripts/rural_division_count.py`, exploratory, hypotheses frozen in the script header before execution; full results at `findings/rural_division_count.md`). The direction reverses: under the audit's established name classifier the 2019 map has 31 rural-anchored divisions, the majority 28 (three absorbed into urban-anchored successors, six amalgamated into three, three new rural divisions created, one of them Spruce Grove, a bare city name the classifier counts as rural), and the minority 23 (seven absorbed into urban-anchored successors, plus Banff-Kananaskis and Rimbey-Rocky Mountain House-Sundre amalgamated into the chair-flagged Rocky Mountain House-Banff Park; no new rural division). A hyphen/period-robust sensitivity classifier yields the same ordering (28/24/19). H-charge is not supported; both maps reduce rural-anchored divisions relative to 2019 — the charge's underlying observation, consistent with Recommendation 5's call for added rural seats — but comparatively the accusation lands on its author. The minority's second measurable charge on the same page — that the majority "decline[d] to use" the ±25% range in rural Alberta — was tested the same day (`analysis/scripts/rural_variance_usage.py`, `findings/rural_variance_usage.md`) and is **supported**: rural-anchored divisions average −6.0% deviation on the majority (4 below −10%) versus −12.2% on the minority (11 below −10%), stable under the corrected classifier. Read together, the two results describe two design philosophies rather than one vice — more-but-fuller rural divisions (majority) versus fewer-but-lighter plus urban-anchored hybrids (minority) — and the audit takes no

position on which better serves effective representation. The audit treats these results and the majority's flags identically: interested-party claims, tested with the same instruments, reported whichever way they cut. The April 16, 2026 floor debate (Hansard, 31st Leg., 2nd Sess., morning sitting; mined 2026-07-14, `findings/hansard_april16_motion19.md`) adds the legislative context: no member — government or opposition — criticized the majority report on the floor; the government presented its motion as implementing the majority chair's own addendum, and the opposition demanded the majority report's adoption. The written charges against the majority map exist only in the minority report's own pages.

Counter-test 1 — Edmonton zone packing. Classify Edmonton EDs into Zone C (north of the North Saskatchewan River) and Zone D (south of the river). Compute the C-vs-D mean-population gap. Compare to the Calgary Zone A-vs-B gap. Result: Zone D's mean population exceeds Zone C's by 2.0 pp under the majority map and 1.5 pp under the minority map (in percent of the provincial mean), both far below the minority map's Calgary Zone A-vs-B gap of 12.1 pp in the same units (6,656 ÷ 54,929; §5.1.2 gives it as 12.2 % of the Zone B mean). The Calgary finding survives symmetry of test selection: no equivalent zone asymmetry exists in Edmonton under either map. The Calgary zone gap is a minority-map-specific feature, not an artefact of selecting a Calgary-zone test (the formal packing signature itself is not detected; §5.3.1).

Counter-test 2 — City-wide 4-way split. For every Alberta municipality with population ≥ 50,000 (excluding Calgary and Edmonton, whose populations exceed three statutory quotas and force multi-way splits), identify any city split across four or more EDs in either map. Results:

CITY	MAJORITY MAP	MINORITY MAP
Airdrie	2 EDs	4 EDs by territory, 3 by people (C48)
Lethbridge	**2 EDs**	**4 EDs — new finding**
Red Deer	**2 EDs**	**4 EDs — new finding**
Medicine Hat	2 EDs	2 EDs
St. Albert	2 EDs	3 EDs
Grande Prairie	2 EDs	2 EDs
Lloydminster	1 ED	1 ED

Two new minority-specific cracking-candidate patterns emerge: Lethbridge 4-way (Lethbridge-Cardston, Lethbridge-Fort MacLeod-Crowsnest Pass, Lethbridge-Little Bow, Lethbridge-Taber-Warner) and Red Deer 4-way (Red Deer-Blackfalds, Red Deer-Innisfail, Red Deer-Lacombe, Red Deer-Sylvan Lake). The majority map applies 2-way splits to both cities. ***Federal context.*** *Under the 2023 Representation Order, Airdrie, Red Deer and Lethbridge each sit within one federal riding. The federal quota (about 115,000) is about twice the provincial one, so at the provincial quota each needs at least two districts. This is context, not a benchmark. Pending C2 / C3 threshold tests (see §5.3.2 for the formal cracking-signature methodology), these are cracking-candidate findings rather than formally-detected cracking signatures. With Airdrie (four districts by territory, three by people), they form a pattern of three Alberta cities that the minority map divides into more pieces than the two the majority uses, which is the minimum for each.*

Pre-registration caveat for the Lethbridge and Red Deer findings. The counter-test framework was specified and executed in the same analytical pass. The symmetry criteria are prose-level and the city-population threshold (≥ 50,000 residents) is geographically anchored

rather than retrofitted, but the finding was not independently pre-registered before execution. These two cracking candidates are therefore held separately from the formal cracking test in §5.3.2: Airdrie was scored against C-criteria set before the detection run, and on the official boundaries it fails C2 (DOCUMENTED CORRECTIONS C48). Lethbridge and Red Deer are symmetric-test-derived patterns matching Airdrie's split structure but have not been scored against the same formal gate. They are reported because the symmetric test found them. They should not be counted as formal signatures until the C-criteria run produces threshold values for each city.

Interpretation. The audit's symmetry-of-test-selection claim is strengthened by the Edmonton counter-test (Calgary zone asymmetry is not a test-selection artefact) and extended by the Lethbridge and Red Deer findings (the split pattern identified at Airdrie reproduces elsewhere). The counter-test framework is now a reusable audit discipline: any reviewer who proposes a new symmetric test can run it against both maps via the same script and record the result. The script's per-city output, `data/outputs/majority_symmetry_counter_test.csv`, counts the districts whose names carry the city's name, and it does not reproduce the table: it gives the minority two Airdrie and two St. Albert districts and has no Lloydminster row. The table's Airdrie row follows C48, and its St. Albert, Lethbridge and Red Deer rows agree with the official-boundary intersection in §5.8.4 (`findings/municipal_splits.md`).

Counter-test 3 — Majority rural-isolation (T3.2; intra-session exploratory, 2026-06-11; reclassified 2026-06-12 per T1.7 Referees #4 and #11; salt `t3_2_majority_rural_isolation_counter_test` declared but never consumed by the deterministic implementation). The original motivating statistic — majority drain z = −2.915 — was substrate-stale (DPG/blended-vote substrate) and mislabeled as "against the canonical 1.01M-plan ensemble" when it was actually a label-shuffle null. Canonical Phase B re-run (`findings/drain_label_shuffle_null_canonical.md`) gives majority z = −3.173 against the canonical-substrate label-shuffle null, with all three maps (2019 z=−3.520, majority z=−3.173, minority z=−2.750) anomalously low and 2019 enacted the most anomalous. Two competing readings — H_0 (Alberta's statutory rural carve-outs naturally produce isolated rural EDs) vs H_1 (the majority engineered elongated rural corridors that minimize urban contact) — were proposed in `preregistration/t3_2_majority_rural_isolation_design.md` at commit `8701408` 85 seconds before result `3bfeefa` landed; the test is therefore **intra-session exploratory**, not pre-registered confirmatory. Three independent rural-isolation metrics were measured on majority 2026, minority 2026, and the 2019 enacted map (geographic control): R1 median Polsby–Popper of rural-anchored EDs (lower = more elongated); R2 mean count of urban-anchored neighbors per rural ED (lower = less urban contact); R3 fraction of rural EDs with zero urban-anchored neighbors (higher = more isolation). Result:

MAP	N RURAL EDS	R1 MEDIAN PP	R2 URBAN-NBRS/RURAL	R3 FRAC WITH 0 URBAN NBRS
Majority 2026	28	0.347	2.143	0.107

MAP	N RURAL EDS	R1 MEDIAN PP	R2 URBAN-NBRS/RURAL	R3 FRAC WITH 0 URBAN NBRS
Minority 2026	23	0.397	2.478	0.043
2019 enacted (control)	31	0.387	1.774	0.258

The design document's decision rule scores majority rank-1 on only one of three axes (compactness only); the 2019 enacted map — the geographic baseline drawn under the same Alberta s.15(2) carve-outs — is the most rural-isolated map on R2 and R3 and the second-most on R1. ***Verdict: H_0 supported.*** *The majority's anomalously low drain score is consistent with natural Alberta rural geography rather than engineered rural isolation. Notably, the minority is the least rural-isolated map on all three metrics, consistent with its greater use of urban-rural hybrid districts. Full result at* `findings/t3_2_majority_rural_isolation.md`.

5.7 Stress-test grades mini-audit

The paper reports stress-test outcomes against the gates RT1–RT6 listed above. To make the grade structure auditable rather than rhetorical, the table below lists each gate's pre-registered numeric threshold alongside the observed value, per ASA (2016, 2019), Nosek et al. (2018), and Munafò et al. (2017) guidance on graded evidence reporting.

GATE	PRE-REGISTERED THRESHOLD	OBSERVED VALUE	OUTCOME
RT1 — Monte Carlo 95% CI	Same-sign bounds for strong pass	**[RETIRED, C11]** Historical result [−3.04, +0.76] pp crossing zero, 90.5% direction consistency, quantified uncertainty in the blend model retired 2026-05-18; `monte_carlo_ci.py` cannot currently run, so this gate is not reproducible against the current codebase. Supplementary (non-pre-registered) evidence: attribution-method sensitivity (§5.2.7) finds the minority's headline EG stable to within 0.07 pp across three independent methods.	Gate not reproduc as origin specifiec note); direction consiste preserve under th supplem check

GATE	PRE-REGISTERED THRESHOLD	OBSERVED VALUE	OUTCOME
RT2 — Cross-metric agreement	≥3 of 4 same sign for strong pass	**Post-correction (2026-06-12; Amendment 5, Part 9): B2, B3, B4, B6 all directionally agree (UCP-favoured side). Three carry tail flags (MM p99.97, declination p98.79, s50 p99.99); EG p94.54 is sub-threshold but directionally aligned.** Earlier draft graded 3-of-4 with declination opposing — that was a swapped-operand artefact (see Amendment 5, Part 9).	**4-of-4 s sign (str pass on direction of-4 wit flags**

GATE	PRE-REGISTERED THRESHOLD	OBSERVED VALUE	OUTCOME
RT3 — Cross-election stability	Same direction across 3 election baselines	**Corrected 2026-06-13 per T1.7 R2 S5.** The "+0.30/+0.90%" figures cited in the prior regrade were superseded v0_7 values. **Canonical Option C (100k-plan ReCom, seed 3562959107, area-proportional VA attribution on 4,765-VA substrate — the same canonical 2019 ensemble referenced in §5.2.8) gives: 2019 Majority EG = −1.32 % (p48.3), Minority EG = −0.49 % (p70.4), both NDP-favourable.** EG sign flips from UCP-favoured (2023) to NDP-favoured (2019) for both maps. The earlier claim "no canonical 2019 ensemble computed" was false — Option C is that ensemble. The inter-map asymmetry does not reverse: the minority stays the more UCP-favourable map in all three elections (Option C: +2.96 pp 2015, +0.83 pp 2019, +3.92 pp 2023), but the 2019 value is about a fifth of the 2023 value.	Fails on magnitu passes o directio (asymme same sig all three election 0.83 pp 2019 is than 50 below 3 under 2 the pre-registere Thresho #27 fail both ma signs flip under canonica 2019; th outlier c is bound 2023 electoral context §1.2 correcte caveat).
RT4 — Structural vs vote-based separation	Clear labelling required	Labelling present in §4, §6.2	Pass

GATE	PRE-REGISTERED THRESHOLD	OBSERVED VALUE	OUTCOME
RT5 — Independent test selection	No test run and discarded	Audit-trail clean; counter-test §5.6 added	Pass
RT6 — Assumption inventory	Listed in `analysis/methodology/shapefile_uncertainty_analysis.md`	Listed, but not current: the inventory describes the analysis before the official shapefiles, and its load-bearing Assumption 1 is the 70/30 blend retired 2026-05-18 (RT1)	Pass on listing; inventor current
RT7 — MCMC neutral-ensemble outlier	Any real map outside 5–95 band on ≥1 metric for flagged pass	**Canonical-substrate refresh 2026-06-12 (T1.7 Ref #17 C1):** under the 1,010,000-plan canonical run (§5.4.9), Majority MM p0.99 (NDP-tail) + EG p16.5 + s50 p78.5 (band); Minority MM p99.97 + Decl p98.79 (UCP-tail under Amendment 5, Part 9) + s50 p99.99 + EG p94.54 (sub-p95; directionally aligned but not flagged). Earlier Run #3 (250k, v0_7 centroid) numbers are superseded by the canonical ensemble; the gate's earlier "pending" status is closed.	**Flagged on minc on 3 of partisan metrics + Decl over p9 p94.54 threshol directio aligned) MM tail on majo canonic 1.01M ensembl**

The audit reports each gate's outcome literally (pass / qualified / fail) rather than collapsing into a single pass-grade.

5.8 Geographic coherence

5.8.1 Visual spatial audit

Direct inspection of published commission maps using Opus/Sonnet 4.x vision. Images inspected:

Majority — Appendix A (eight panels, full provincial coverage):

- `data/maps/hires/v0_1_majority_p71_alberta_overview.png` — Alberta overview
- `data/maps/hires/v0_1_majority_p73_calgary.png` — Calgary detail
- `data/maps/hires/v0_1_majority_p75_edmonton.png` — Edmonton detail
- `data/maps/hires/v0_1_majority_p77_near_calgary.png` — near-Calgary
- `data/maps/hires/v0_1_majority_p79_near_edmonton.png` — near-Edmonton
- `data/maps/hires/v0_1_majority_p81_north.png` — north Alberta
- `data/maps/hires/v0_1_majority_p83_central.png` — central Alberta
- `data/maps/hires/v0_1_majority_p85_south.png` — south Alberta
- `data/maps/hires_v2/v0_2_render_majority_calgary_MAP_p72_r1200.png` — 1200-DPI render, primary inspection source for majority Calgary

Minority — Appendix E:

- `data/maps/hires/v0_1_minority_p359_map73.png` — Appendix E map 73
- `data/maps/hires/v0_1_minority_p360_map74.png` — Appendix E map 74
- `data/maps/hires/v0_1_minority_p361_map75.png` — Appendix E map 75
- `data/maps/hires/v0_1_minority_p362_map76.png` — Appendix E map 76
- `data/maps/hires_v2/v0_2_native_minority_min_map_calgary_p101.jpeg` — native extraction, minority Calgary
- `data/maps/hires_v2/v0_2_native_minority_min_map_edmonton_p107.jpeg` — native extraction, minority Edmonton

Full majority panel coverage across all eight Appendix A panels was extracted in sessions 11–12 (Tier-0 raster pipeline). The §5.8.3 symmetric anomaly scan applies to all majority panels, not Calgary only.

5.8.2 Chair-flagged boundaries (C3)

Four boundaries were flagged by name in the majority report's response section. Direct inspection results:

- **Calgary-Nolan Hill-Cochrane (minority): Confirmed.** A district reaching from Cochrane (outside Calgary's western boundary) eastward through a narrow-waisted corridor to Calgary's Nolan Hill neighborhood, skipping Rocky Ridge / Tuscany.
- **Rocky Mountain House-Banff Park (minority): Confirmed.** SW extension of the district traces Banff National Park to reach the BC border. Absent the extension, the district still meets 4 of 5 §15(2) criteria on the predecessor footprint ((a) needs more than 20,000 km², and the 2019 predecessor alone is 24,468 km², §5.9.6; Clearwater County's 18,692

km² would not meet it on its own; (b), (c), (d) all pass without NP territory); the extension adds only criterion (e) — the BC-border coterminous test. See §5.1.4 re-audit.

- **Olds-Three Hills-Didsbury (minority): Confirmed.** Named for three small towns; extends south past Didsbury to take about 23 km² of north Airdrie, but fewer than 400 of its residents (under 1 % of the city; `data/outputs/airdrie_split_shares_2026-10-31.json`).
- **Calgary-Foothills-Airdrie West (minority):** Boundary connection between Calgary-Foothills and Airdrie West tracks a primary highway corridor; the geographic connection itself is defensible, but this ED is one of four making up the Airdrie split (C4).

Combined criticism count across the majority report. The four geographic anomaly flags above are one subset of the commission majority's criticism. On pp. 59 and 62–63 of the final report (§5.9.4 of this audit), the majority also said, writing as "we", that the minority's configurations for five places — Airdrie, Cochrane, Chestermere, Red Deer, and St. Albert — had no public support in the consultation record. Taking the union across both, seven distinct minority configurations were criticized by the majority: the four geometric flags (Calgary-Nolan Hill-Cochrane, Rocky Mountain House-Banff Park, Olds-Three Hills-Didsbury, Calgary-Foothills-Airdrie West) plus three appearing only in the public-support statements (Chestermere, Red Deer hybrids, St. Albert). Cochrane and Airdrie appear in both lists. The audit's §1.1 headline "three geographic anomalies" reflects only the three flags for which the anomaly was confirmed and the geographic rationale was not independently defensible. The full scope of the majority's documented objections spans seven configurations.

5.8.3 Majority hybrids — symmetric check

Applied the same anomaly-scan questions (lasso shape, engineered statutory boundary, misnamed municipality capture) to the majority's four Calgary hybrids:

- **Calgary-East:** Intra-city rectangular block, no extension beyond city limits. No anomaly.
- **Calgary-Falconridge-Conrich:** NE Calgary + directly-abutting Conrich community. Compact. No anomaly.
- **Calgary-Glenmore-Tsuut'ina:** Large southern extension to include the Tsuut'ina Nation reserve; shape tracks the reserve boundary. No anomaly; positively, the reserve is kept intact in a single named ED.
- **Calgary-West-Elbow Valley:** Calgary SW + directly-adjacent Elbow Valley subdivision. No anomaly.

Qualification. The anomaly-scan question set was developed from observed minority anomalies. The majority may have different classes of anomaly (e.g., rural-district highway corridors) not detected by the scan criteria applied here. All eight Appendix A panels have been inspected. The limitation is the question set, not the imagery.

5.8.4 Community-of-interest splits (C4)

DIMENSION	MAJORITY 2026	MINORITY 2026
Lasso/corridor shapes (visible)	0	1 (Calgary-Nolan Hill-Cochrane)
Engineered statutory boundary	0	0 (the commission majority objects to the RMH-Banff Park extension; the signature is not detected, Reading B withdrawn — §5.3.3)
Community captured under misnamed ED	0	1 (Olds-Three Hills-Didsbury → north Airdrie land; under 1 % of Airdrie's residents)
Airdrie split	2 EDs	4 EDs by territory, 3 by people
Cochrane	intact	merged into Calgary
Chestermere	intact	partially split
Tsuut'ina Nation	single ED, named	single ED, named
Enoch Cree Nation	with Edmonton only	bundled with Devon (about 10–15 km S)
Siksika Nation	High River-Vulcan-Siksika (named)	almost all in Drumheller-Stettler (not named)

First Nations representation: Enoch Cree Nation vs. Tsuut'ina Nation. *The two rows above highlight a differential treatment of near-city First Nations reserves the table alone does not make legible. Both Tsuut'ina Nation (Reserve 145, immediately southwest of Calgary) and Enoch Cree Nation (Reserve 135, immediately west of Edmonton along the Highway 16A corridor) are Treaty-recognized nations whose reserves are geographically adjacent to a major Alberta city, with community orientation, urban services access, and civic relationships primarily tied to the adjacent urban area.*

The majority map treats the two nations consistently: Tsuut'ina is in a single named Calgary ED (Calgary-Glenmore-Tsuut'ina) whose boundary tracks the reserve perimeter — the §5.8.3 anomaly scan found no anomaly. Enoch Cree is in an ED linked to Edmonton's west-side geography, consistent with the reserve's position on the Edmonton fringe.

The minority map is consistent for Tsuut'ina (single named ED, reserve-adjacent, no anomaly flagged) but diverges for Enoch Cree. The minority creates Edmonton-Enoch-Devon, pairing Enoch Cree Nation with the Town of Devon to the south (9.1 km apart at the nearest edges and 14.6 km centre to centre, on 2021 census subdivision polygons). Devon (~6,500 residents) is a residential municipality on the North Saskatchewan River whose service geography is oriented toward the Leduc–Edmonton International Airport–Nisku employment corridor, not toward the Stony Plain/Spruce Grove/Highway 16A corridor where Enoch Cree Reserve 135 sits. The natural community-of-interest relationship for Enoch Cree — proximity to Edmonton, shared Edmonton-zone health authority, Edmonton-area commerce — is with Edmonton's west-side EDs, not with Devon.

The geometric consequence on canonical substrate is small: Edmonton-Enoch-Devon's canonical Polsby-Popper score is **0.534**, within the central band of the 178-ED joint set. The v0_9 DPG-era reading of **0.065** (cited in earlier drafts as evidence of "L-shaped corridor" geometry) is **substrate-stale and superseded** for any geometric-consequence claim 2026-06-12 per T1.7 Referee #10 — the v0_9 figure was a DPG transcription artefact, not a real

corridor signature; the canonical EA shapefile PP shows the district is normally compact. The audit's COI critique of pairing Enoch Cree with Devon (about 10–15 km south, different service geography) **stands on the community-of-interest grounds described above**, not on the geometric ground that an earlier draft asserted. Geometric corridor evidence for Enoch-Devon is *not* present on canonical substrate; the COI critique is the load-bearing finding here.

The audit does not file this as a gerrymander signal for two reasons. First, the community-of-interest comparison has now been checked against StatsCan Table 98-10-0459 (journey-to-work) for the Enoch Cree CSD (DGUID `2021A00054811804`; data at `data/outputs/enoch_cree_journey_to_work.csv`, downloaded 2026-06-13): of 435 Enoch Cree resident workers, **255 (58.6%) work on-reserve**, **100 (23.0%) commute to the City of Edmonton**, 20 (4.6%) to Spruce Grove, and 10 each to Stony Plain, St. Albert, Parkland County, Leduc County, and Leduc City. **Devon does not appear as a commute destination at any non-zero count level.** Commutes run mainly east and west (Edmonton 23%, then Spruce Grove and Stony Plain on the Highway 16A corridor), with 20 workers going south and southeast to Leduc County and Leduc, and none recorded to Devon (about 10–15 km south). The claim that Enoch Cree's natural service relationship is with Edmonton rather than Devon is now documented at CSD commuter-flow resolution, not merely geographically inferred. Second, the pairing may be constrained by population math: if the combination of Enoch Cree (on-reserve population ~1,000–1,500) and adjacent Edmonton west-side EDs leaves no legal configuration within the ±25% statutory band, the Devon bundling may be the closest available compliant option. The population arithmetic for this choice has not been separately verified.

What is documented is the asymmetry relative to Tsuut'ina: the minority applies the "single named ED, reserve-adjacent, no anomaly" standard to Tsuut'ina and does not apply it to Enoch Cree. The commission's rationale in Appendix E does not address this differential treatment.

Census-subdivision-level robustness check. A CSD-level overlay (Track H; script `analysis/scripts/csd_community_splits.py`) computes, per map, the count of populated CSDs (population ≥ 1,000) spanning two or more electoral divisions. Under 2019 boundaries (measured via geopandas overlay on `data/shapefiles/reference/alberta_2019_eds/`): 66 of 191 populated CSDs (34.6%) are split. Under the majority 2026 proposal (inferred via the Appendix C crosswalk): 66 of 191 (34.6%). Under the minority 2026 proposal (inferred, lower bound, via the heuristic crosswalk): 54 of 191 (28.3%). Upper bound matching the 2019 count of 66. On the confident-only subset of 139 CSDs (excluding those touched by minority-crosswalk uncertainties or any hybrid), all three maps produce the same 40 splits. **On these crosswalk-inferred counts, the Majority-minus-Minority asymmetry visible in the table above does not show; the direct intersection on the official boundaries below does show it (10 split municipalities against 20).** The minority's community-of-interest disadvantage operates at within-ED partition resolution (e.g., the four-way partition of the City of Airdrie, the bleed of Chestermere into Calgary-Peigan-Chestermere) — a resolution not

encoded in the ED-level crosswalks. The within-ED qualitative findings in the table above remain the reported finding. The crosswalk-inferred 2026 counts predate the official shapefiles and are superseded by that intersection, which covers a different set of municipalities.

Spatial CSD fragmentation analysis (official Elections Alberta canonical geometry; script `analysis/scripts/municipal_splits.py`; corrected and rerun 2026-07-13, DOCUMENTED CORRECTIONS C12). A direct intersection of the canonical EA boundaries against Statistics Canada 2021 CSD polygons, restricted to Cities (CY), Towns (T), Specialized Municipalities (SM), Villages (SV), and Improvement Municipalities (IM) with ≥ 300 VA votes (~3,000 residents), measures how many EDs each municipality is split across. Unlike the crosswalk-inferred method above, this uses geometric intersection, requiring both a ≥ 50 ha absolute overlap *and* ≥ 1% of the municipality's own area to count as a real split (see C12 for why the threshold changed from a 5 ha absolute-only floor).

MAP	MUNICIPALITIES SPLIT ACROSS ≥2 EDS	CHANGE VS 2019
2019 enacted	10	baseline
Majority 2026	10	**+0**
Minority 2026	20	**+10**

The majority map leaves the set of fragmented municipalities unchanged from 2019 (the same ten stay split; Calgary and Edmonton each pick up one additional ED, +1 apiece, but no municipality newly crosses the ≥2-ED threshold). The minority map doubles the fragmented-municipality count: it splits ten more municipalities and divides four already-split cities further. The four are Red Deer (2→4), Lethbridge (2→4), Airdrie (2→4 by territory) and St. Albert (2→3); the ten are towns/counties moving from unsplit to a 2-way split (Okotoks, Chestermere, Stony Plain, Sylvan Lake, Canmore, Blackfalds, Lac la Biche County, Coaldale, Crowsnest Pass, Devon). The Red Deer and Lethbridge 4-way splits corroborate the independently-computed Counter-test 2 findings below (§5.6). Strathcona County — cited in earlier drafts of this section as the headline single case (3→10 EDs under the minority) — does not actually change under either map once boundary-following slivers below the 1%-of-area floor are excluded: it remains split across the same 3 EDs (Fort Saskatchewan-Vegreville, Sherwood Park, and the Strathcona-named ED) under 2019, the majority, and the minority alike. That earlier Strathcona finding rested on data that had never been recomputed on canonical geometry at all (a silent column-name mismatch left the script raising an exception on every run since the 2026-05-06 shapefile switch, so the report was citing a stale April run); a first attempt to fix it inherited a second, subtler error — the original 5 ha absolute-only slice threshold, calibrated for smoothed DPG-era boundaries, counts numerous sub-0.02%-of-area boundary-touching artifacts in precise official geometry as "splits." Full detail in C12; full per-municipality breakdown at `findings/municipal_splits.md`; data at `data/municipal_splits.json`.

Constitutional and international law dimensions. The boundary decisions analysed above — pairing Enoch Cree Nation (Reserve 135) with Devon rather than with Edmonton west-side geography, while Tsuut'ina Nation (Reserve 145) receives a named district tracking the reserve perimeter — engage constitutional and international legal frameworks that this audit does not assess but that informed readers and the affected nations should be aware of.

Section 35(1), Constitution Act, 1982 provides: "The existing aboriginal and treaty rights of the aboriginal peoples of Canada are hereby recognized and affirmed." Jurisprudence following *Haida Nation v. British Columbia (Minister of Forests)*, 2004 SCC 73, and *Taku River Tlingit First Nation v. British Columbia (Project Assessment Director)*, 2004 SCC 74, establishes that the honour of the Crown gives rise to a duty to consult Indigenous peoples when the Crown contemplates conduct that might adversely affect Aboriginal title or treaty

rights — before decisions are made. Electoral redistribution that alters the electoral district to which a reserve is assigned is the type of Crown conduct that may engage this duty: the assignment determines which community the nation is paired with for the purpose of choosing a provincial representative, and in the minority map's Enoch Cree configuration, the assignment pairs the nation with a municipality (Devon) with which it has no documented commuter, commercial, or service-provision link. The extent to which Alberta's redistribution process did or did not satisfy any s.35-derived consultation obligation — including the threshold question of whether such an obligation was triggered — is a legal question the audit does not adjudicate. The audit's statistical and geospatial findings (no recorded commute flow to Devon; commutes mainly toward Edmonton) may constitute relevant evidence in such an inquiry.

Article 18 of the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) provides: "Indigenous peoples have the right to participate in decision-making in matters which would affect their rights, through representatives chosen by themselves in accordance with their own procedures, as well as to maintain and develop their own indigenous decision-making institutions." Canada gave domestic legal effect to UNDRIP through *An Act respecting the United Nations Declaration on the Rights of Indigenous Peoples* (Bill C-15, 2021), which commits the federal government to align federal laws and policies with UNDRIP. Alberta has not enacted equivalent provincial UNDRIP legislation as of June 2026. However, Article 18 speaks directly to the right of Indigenous peoples to participate in decisions affecting which representatives will speak for their communities. A redistribution process that pairs a First Nation's reserve with a distant municipality — without documented engagement with the nation's own consent or preference — engages the Article 18 principle at a minimum as a matter of interpretive context for any s.35 consultation analysis. Whether the Article 18 standard was met is for Enoch Cree Nation and its counsel to assess.

Tsuut'ina–Enoch Cree differential treatment, summary. The documented asymmetry — Tsuut'ina Nation (Reserve 145) receives a named, boundary-tracking single district under both maps; Enoch Cree Nation (Reserve 135) receives a Devon pairing under the minority map with zero commuter flow documented to Devon — is the factual predicate for both the s.35 and Article 18 framing above. The commission's Appendix E provides no rationale for the differential. Whether the differential treatment reflects population-math constraint (no legally compliant configuration pairing Enoch Cree with an Edmonton west-side ED within the ±25% statutory band) or a deliberate community-of-interest choice has not been separately verified by the audit; the population arithmetic for this choice remains open.

5.8.5 Municipal-boundary anchoring audit — did not survive canonical recomputation

The pre-registered municipal-anchoring test measures the percentage of each map's ED perimeter falling within 500 m of a Statistics Canada CSD edge (script: `score_anchoring.py`; qsgy8 registered a 50 m tolerance, so the script's 500 m departs from it). Canadian redistribution commissions typically follow municipal boundaries where

the population math permits, so the share of perimeter aligned with CSD edges is a meaningful proxy for adherence to the standard Canadian community-of-interest convention.

Contiguity filter (flagged missing 2026-06-12 per T1.7 R2 Ref #10; landed the same day as T4.10-anchor). The pre-registration specifies measurement only over *contiguous ≥ 1 km segments* of aligned perimeter. `score_anchoring.py`'s `_measure_ring()` implements this run-length filter directly (accumulating contiguous snapped-segment runs and counting only those ≥ 1,000 m). The values below are the filtered result, rerun 2026-07-12 (`data/outputs/municipal_anchoring_canonical.json`). The minority's canonical 71.8 % is 3.3 pp below the 2019 map's 75.1 % on the same measure.

Canonical result (official Elections Alberta shapefiles, contiguity-filtered, rerun 2026-07-12):

MAP	ANCHORED FRACTION	DIFFERENCE FROM THE 2019 MAP
Majority 2026	**80.0 %**	+4.9 pp
Minority 2026	**71.8 %**	−3.3 pp
2019 enacted (baseline)	**75.1 %**	—

Ratio majority/minority = 1.11×. Both 2026 maps are close to the 2019 map's 75.1 %. The minority sits slightly below the majority. (An earlier "70–85 % Canadian comparator norm" had no source and is not used; C49.) The anchoring dimension does not produce a structural-divergence signal on canonical geometry.

Pre-shapefile history. During the audit's pre-canonical phase (April 2026), the same script run against the DPG (Derived Provisional Geometry) v0_10 substrate returned minority 14.5 %, majority 71.0 %, ratio 4.9× — reported as the structural lane's cleanest single signal. The result did not survive canonical recomputation. The footnote attached to this section gives the full mechanism (area-vs-perimeter fidelity distinction in the DPG pipeline) and disposition.[3]

The audit's structural case (§5.0.1, §6.2.2) consequently rests on the four geometry-independent dimensions — population dispersion (on the commission's 2024 tables, not on the 2021 census; Appendix C), Calgary zone asymmetry, Airdrie fragmentation, and chair-flagged spatial anomalies — together with the MCMC ensemble (Mahalanobis $p \approx 8.80\times10^{-7}$, a model estimate extrapolated past every sampled plan; the sample alone supports p below about 6.9×10^{-4}).

Schools as a community-of-interest tie — partly supported, partly untested. Two minority configurations cite schooling as a tie. Calgary-Bow-Springbank (AEBC, 2026, Appendix E, p. 324) invokes "educational institutions" as a community-of-interest tie between Springbank and west Calgary. Springbank's public schools are in Rocky View School Division No. 41 and west Calgary's in the Calgary Board of Education, but the rationale does not claim a shared division, and "educational institutions" was not tested against data that measures it. Red Deer–Sylvan Lake (AEBC, 2026, Appendix E, p. 351) says rural residents "go to school" in the urban centre. Sylvan Lake's public schools are in Chinook's Edge School Division No. 73 and Red Deer's in Red Deer Public Schools, but Red Deer Catholic Regional Schools serves both

Red Deer and Sylvan Lake, so the "go to school" tie is partly supported. Neither rationale claims a shared school division.

The pattern is structural, not isolated. An audit of all 21 minority hybrids against Alberta Education school-division boundaries (`analysis/methodology/reference/school_division_coherence.md`) finds **20 of 21 cross at least one school-division boundary** — a mathematical consequence of Alberta's school divisions being built around municipal limits (CBE ends at Calgary's limits, Red Deer Public at Red Deer's, Edmonton Public at Edmonton's) and the minority's hybrid doctrine explicitly crossing municipal limits. All four Red Deer hybrids (Blackfalds, Innisfail, Lacombe, Sylvan Lake) cross public school-division boundaries — not just Sylvan Lake. The structural school-division crossings are not by themselves gerrymander signals on the school dimension, and because neither R5 nor R11 claims a shared division, the division boundaries do not refute them (above). Full per-hybrid classification (school-coherent / mildly incoherent / severely incoherent / neutral) in `analysis/methodology/reference/school_division_coherence.md`.

Cochrane commuter-tie claim — partial support at CSD resolution. The Calgary-Nolan Hill-Cochrane hybrid is defended by the minority report (AEBC, 2026, Appendix E) partly on the claim Cochrane residents "move fluidly" between Cochrane and Calgary. StatsCan Table 98-10-0459 (2021 Census journey-to-work) disaggregates Cochrane CSD commute destinations: of 8,550 Cochrane workers with a usual place of work, 4,205 (49.2%) work within Cochrane, 3,065 (35.8%) commute to Calgary CY, 345 (4.0%) to Rocky View County, 185 (2.2%) to Canmore, 135 (1.6%) to Wood Buffalo, and 130 (1.5%) to Airdrie. The Calgary flow is a genuine commuter-tie signal at the city-to-city level. The 2021 public release collapses Calgary to a single CSD and cannot test the within-Calgary sub-destination, so the pairing of Cochrane specifically with the Nolan Hill/Sage Hill ward is neither confirmed nor refuted by this dataset. The interpretive inference — Nolan Hill is a residential neighbourhood without significant employment and is therefore unlikely to be the commute destination for the 35.8% Calgary-bound flow — is consistent with the city's land-use profile but does not derive from the StatsCan data directly. Full methodology in `analysis/methodology/reference/cochrane_journey_to_work.md`.

Piikani name-etymology note. The name "Peigan" in the existing Calgary-Peigan electoral division and its minority extension Calgary-Peigan-Chestermere derives from Peigan Trail SE, a road forming the district's northern boundary, not from a community-of-interest tie to the Piikani Nation (whose Piikani 147 reserve is located approximately 200 km south of Calgary, near Pincher Creek and Fort Macleod). The minority's retention of the name in the hybrid extension preserves a road-based etymology. This is a naming observation, not a finding of fault.

Community of Interest: Legislation vs. Practice. Neither the federal *Electoral Boundaries Readjustment Act* nor Alberta's *Electoral Boundaries Commission Act* provides a strict definition for "community of interest." In Canadian redistricting practice, independent commissions rely heavily on municipal boundaries as the primary objective proxy for

shared community concerns (Courtney 2001, chs. 6–7). Elections Alberta told the audit that, for communities of interest, the commission used "the ESRI and Google basemaps for references" and members' knowledge from public hearings (personal communication, 2026-05-07; `analysis/methodology/canonical_shapefile_log.md`). That describes the whole commission, not the minority report, which does not use those words. Elections Alberta also said it uses Alberta OpenData municipal boundaries; the audit's anchoring uses Statistics Canada 2021 census subdivisions, a different source. On canonical geometry the quantitative anchoring gap is small (71.8 % minority vs 80.0 % majority, both close to the 2019 map's 75.1 %), and the previously-cited 4.9× anchoring statistic does not survive.[3]

5.9 Procedural findings

5.9.1 Commission operation

Five-member commission constituted under s. 2(1) of the Electoral Boundaries Commission Act: chair appointed by the Lieutenant Governor in Council (s. 2(1)), two government-nominated commissioners, two opposition-nominated commissioners. The commission submitted its interim report on October 27, 2025 (final report p. 13). Its divided final report (3–2) is dated March 23, 2026, and was tabled by the Speaker on March 26, 2026 (Sessional Paper 436/2025-26). The three-member majority comprises the chair plus the two opposition-nominated commissioners. The Legislative Assembly's notice of the appointments ("Electoral Boundaries Commission to soon begin consultations", March 28, 2025, https://www.assembly.ab.ca/about/news-and-announcements/2025/03/28/electoral-boundaries-commission-to-soon-begin-consultations; archived at `evidence/legislature/assembly_news_ebc_appointed_2025-03-28.html`) lists Dr. Julian Martin and John D. Evans, KC as "Nominated by the President of Executive Council", and Greg Clark and Susan Samson as "Nominated by the Leader of His Majesty's Loyal Opposition". The minority report is Martin's and Evans's.

5.9.2 April 16, 2026 government action

In April 2026 the Alberta Legislative Assembly set the commission's reports aside. Government Motion 37, introduced April 16 and passed April 21, 2026, established a Select Special Committee of six MLAs (four UCP, two NDP) chaired by Brandon Lunty, MLA for Leduc-Beaumont, to oversee an independent review of the boundaries (Legislative Assembly of Alberta, committee page). The committee was served by an Independent Advisory Panel, which drew a 91-seat map and delivered its report to the committee on October 22, 2026; on October 28 the committee voted 3–2 to end its review without observations, and it had to table the report by November 2 (committee transcript, pp. CEB-72 and CEB-74). The panel had two members nominated by the Premier and two by the Leader of the Opposition, appointed June 9, 2026, with retired Court of Appeal justice Brian O'Ferrall later named chair after Alberta's acting chief justice declined to help find a judicial

chair, citing "the irregularity of this process" (Assembly news release, June 9, 2026; Southern Alberta Newspapers, May 28, 2026; CTV News). Unlike the commission it replaced, the new process did not include public hearings on a draft map.

Relationship to Chair Miller's Recommendation 5. The Premier framed the April 16 motion as aligned with a recommendation by Chair Dallas Miller (Government of Alberta press remarks, April 16, 2026, as reported in Rimbey Review; Calgary Journal, April 21, 2026). This framing is traceable to the Chair's Addendum to the Majority Report (AEBC, 2026, pp. 66–67), which proposed **Recommendation 5**: in the event the Legislature could not accept the majority's 89-seat boundaries, the Act should be amended to raise the seat count from 89 to 91 through "an all-party Select Special Committee or other equivalent Legislative Committee," restoring the two rural divisions the majority report removed while maintaining "the rest of the province as we propose... to the extent possible."

Provenance of R5: the chair alone, not the commission majority. The opening sentence of R5 is drafted in the voice of "the majority of the Commission." Chair Miller, however, states in the same addendum: "*My majority colleagues do not agree with me on this point*" (AEBC, 2026, p. 66). On the commission's own documentation, R5 is therefore the personal recommendation of the chair, not a collective recommendation of the three-member majority. The Premier's off-floor framing carries this distinction: the motion "aligns with a recommendation from the commission's chair" (Calgary Journal, April 21, 2026). On the floor she said, "We are supporting the majority report with the recommendation of the judge" (Alberta Hansard, April 16, 2026, p. 1509). The framing is accurate as to the chair's personal position. It overstates the recommendation's provenance if read as a collective endorsement by the majority. Corroboration: CBC News Edmonton, April 16, 2026 ("Miller adding: 'My majority colleagues do not agree with me on this point'"). Full text of R5 is preserved in `findings/chair_recommendation_5_analysis.md`.

The p. 58 citation on the floor. In the April 16 debate the Premier read the majority report's p. 58 sentence into the record verbatim, and continued: "in one of their recommendations they say that next time this is done, give the commission the latitude to increase the number of seats. We're following the recommendation of the majority" (Alberta Hansard, April 16, 2026, p. 1509). The citation is accurate as a quotation and narrower as an authority. The same page says the majority would have favoured more seats: had the commission been given the power, "we may very well have proposed a map of at least 91 electoral divisions" (p. 58), and p. 65 says the map "can be greatly improved if more electoral divisions were added". But on p. 58 the attached remedy is prospective and commission-empowering — "One potential remedy for this challenge is for the Legislature to grant future commissions the power to set an appropriate number of electoral divisions" (AEBC, 2026, p. 58; restated in the executive summary as flexibility for "future electoral boundaries commissions", p. 10) — while the report's operative request is that the Legislature "adopt the Commission's proposed set of 89 new electoral divisions" (p. 9). Government Motion 37 exercises the latitude in the current cycle rather than the next, vests it in a committee of MLAs rather than a commission, and declines the operative request. The Premier's fused

floor formulation — "We are supporting the majority report with the recommendation of the judge to not deprive rural Alberta of representation" (Hansard, p. 1509) — thereby attaches the majority's authority to a route its members did not sign: the majority favoured two more seats, but not the chair's committee route or his claim that 91 seats would avoid any rural loss. The record supports the narrower claim that the government used the chair's proposed mechanism; it does not support the broader claim of implementing the majority report. Fair-reading detail and contiguity-verification method: `findings/hansard_april16_motion19.md`.

The alignment between R5 and the April 16 motion is partial on three grounds, addressed individually in `findings/chair_recommendation_5_analysis.md`:

1. **Form.** The vehicle (Select Special Committee raising the count from 89 to 91 for rural-seat restoration) matches R5's specification. The motion can legitimately claim this anchor.
2. **Substantive constraints.** R5(a)–(d) specifies four concrete boundary conditions — no impact on any electoral division in Airdrie or south of it except Drumheller-Stettler. No impact north of Edmonton's North Saskatchewan River. Reversion of south-of-NSR Edmonton districts to the interim-report map. Consideration of restoring a Clearwater County-plus-western-Mountain-View s.15(2) district (scored per Amendment 5, Part 13). Whether the panel's map respects these conditions was not scored before this paper went to press; X1 of the November checklist tests it (see §5.5, §7.2). R5 also requires "the rest of the province as we propose [in the majority report] must be maintained to the extent possible" — a condition the motion does not name: it directs the panel to "incorporate the recommendations provided in Recommendation 5 in the Addendum to the Majority Report subject to any modifications the independent advisory panel considers necessary" (Government Motion 37, C(e)(ii)(B)), and its recital describes those recommendations as R5(a)–(d) (A(i)(iii)).
3. **Intent.** Chair Miller stated R5's purpose directly: it "is formulated for the express purpose of dissuading the Legislature from accepting the minority report" (AEBC, 2026, p. 66). The Chair further described the minority's hybrid configurations in Airdrie, Calgary, Chestermere, Cochrane, Red Deer, and St. Albert as "not something that I can condone" (AEBC, 2026, p. 67). A committee output reintroducing any of those minority configurations invokes the form of R5 while inverting its intent. The motion names no starting map; it points the panel at the majority's divisions only through R5, which the panel may modify as it considers necessary (C(e)(ii)(B)). That discretion, combined with the presence in the committee of the political faction that nominated the minority commissioners (§5.9.1), is therefore procedurally distinct from R5's conditional.

Regional-economy framing. Regional economic groupings have offered partial support for the minority's general hybrid doctrine. The Central Alberta Regional Economic Development Alliance grouped Red Deer, Innisfail, Blackfalds, Lacombe, and Sylvan Lake — the five municipalities at the heart of the minority's Red Deer hybrid proposals — and the

former Calgary Regional Partnership grouped Calgary with Airdrie, Cochrane, Chestermere, Okotoks and Rocky View — the catchment for the minority's Calgary hybrids. No source for either grouping is filed in this repository, and both may have since wound down. They were not, in any case, boundary prescriptions. Any map grouping districts within these zones satisfies the zone-coherence criterion, and the zones do not by themselves justify the specific intra-zone configurations the minority proposed.

5.9.3 Comparator cases

Canadian boundary-commission practice traces to *Reference re Provincial Electoral Boundaries (Saskatchewan)* [1991] 2 SCR 158, which established the "effective representation" standard as the constitutional benchmark for provincial electoral boundaries. *Figueroa v. Canada (Attorney General)* [2003] 1 SCR 912 and *Frank v. Canada (Attorney General)* [2019] 1 SCR 3 developed the broader s. 3 Charter right to vote. Courtney (2001) provides the authoritative scholarly treatment of the independent-commission model across Canadian provinces: chapters 6–7 map the interplay between population equality and community-of-interest discretion, and chapters 10–11 address public-hearing obligations and post-hearing revision scope — all directly relevant to the D1–D4 procedural findings below. Pal (2015) argues the Saskatchewan Reference standard leaves commission members substantial discretion reviewable, if at all, only at the outer margins — not for partisan preference proximity — so the distinction between legitimate design preference and legally reviewable partiality turns on the same factual record the D1–D4 evidence assembles. Pal and Choudhry (2014) examine a related question, how population variance between ridings dilutes the votes of visible-minority Canadians. The procedural findings below are situated within the discretion space: the audit documents where the minority's boundary choices depart from the pattern established by the majority under identical statutory constraints. The legal weight of the departure, if any, is for a reviewing body to assess under Pal's framework.

An earlier Quebec case is weaker than drafts of this paper said. In 2010–11, Bill 132 paused the *Commission de la représentation électorale*'s work; the commission's 2011 map then took effect and was used in the 2012 and 2014 elections. The closer antecedent for legislative interference with a provincial redistribution is Quebec's 2024 freeze (below; §5.9.5).

Federal comparator: the 2022 Federal Electoral Boundaries Commission for Alberta. A second institutional comparator operates at a different level: the 2022 Alberta federal redistribution cycle, conducted under the *Electoral Boundaries Readjustment Act* (R.S.C. 1985, c. E-3). This cycle is relevant because the federal commission (chaired by Justice J.D. Bruce McDonald, with members Donald Barry and Donna Wilson) operated under a statutory mandate structurally identical in its non-quantitative factors to Alberta's provincial Electoral Boundaries Commission Act: both delegated authority to independent, multi-member commissions with comparable discretion over geography, community of interest, and population variance. The federal commission's handling of the same Alberta cities is context for the provincial question, not a benchmark.

Under the 2023 Representation Order, Airdrie (population 74,100 in 2021) sits within one federal riding, Airdrie—Cochrane; Red Deer and Lethbridge each sit within one riding as well. The federal quota (about 115,000) is about twice the provincial one, so the population bases are not the same: at the provincial quota each of these cities needs at least two districts. The majority uses two for each; the minority uses four by territory for each (three by people for Airdrie). §5.6 treats Lethbridge and Red Deer as cracking candidates on the provincial arithmetic alone.

The 2022 federal cycle does not determine the provincial boundary question — the two redistributions operate under different statutory frames, quotas and electoral systems — and the audit's analysis in §5.3.2 and §5.6 does not rest on it.

The April 16, 2026 Alberta motion came after the commission had tabled its final report, and it did not leave the existing map in force: it reassigned the remaining work to a legislature-selected committee (the Lunty committee) and the independent advisory panel the committee engaged. The panel delivered its report and map on October 22, 2026, and the committee had to table it by November 2; this paper went to press before the audit scored it. The reassignment removed the independent commission from the remaining process. Whether the panel's map will be adopted is for the Assembly. Alberta's own 1992 cycle is a different case. After the 1992 commission reported without consensus, the Assembly passed Motion 24 (July 2, 1992) creating a select committee of MLAs chaired by Bob Bogle; PC MLAs alone drew the map after the Opposition declined to take part; the 1993 election ran on it; and the Court of Appeal's 1994 reference let the map stand while faulting the committee for being unable to justify several boundaries and district populations. The Act was amended in 1995 (Bill 20). These details rest on secondary sources; the 1994 judgment was not read for this report. What distinguishes 2026 is narrower: the commission produced a majority report, which s.9 of the Act makes the commission's report, and it was set aside. The constitutional status of this class of interference has since become non-hypothetical: six days after the Alberta motion, the Supreme Court of Canada dismissed Quebec's appeal of a ruling that struck down the Legault government's 2024 statute blocking the *Commission de la représentation électorale* from redrawing Quebec's provincial map. The SCC's 7–2 from-the-bench ruling held the freeze law violated the Charter's democratic-representation guarantee. Whether the Lunty committee structure is constitutionally distinguishable from a legislative freeze — for instance, because it formally reassigns rather than simply blocks, or because Alberta's voter-weight disparities differ from Quebec's — is for a court to decide on its own facts. The doctrinal implications are discussed in §5.9.5.

5.9.4 Public submission record (D2)

The commission received 1,345 written submissions across two rounds of public consultation (198 and 1,147; final report p. 14). The commission majority, writing as "we", states that the minority's recommendations for Airdrie, Cochrane, Chestermere, Red Deer, and St. Albert "do not appear to have any public support" (Alberta Electoral Boundaries

Commission [AEBC] 2026, p. 59) and that "The Commission received no public support whatsoever for the minority's maps for these cities" (p. 62); p. 63 names the Calgary-Foothills-Airdrie West and Calgary-Nolan Hill-Cochrane boundaries.

A keyword search with manual review of the commission's submission archive — 1,252 of the 1,345 submissions extracted with usable text. The remainder (about 93, 6.9%) are image-only scans without machine-readable text or detectable submission-ID markers — tests this claim. One limit governs everything below: no hearing or submission could respond to the minority's maps. Submissions closed on December 19, 2025, the last hearings ended on January 21, 2026, and the minority departed from the interim map in late January (final report pp. 13–14, 62). The counts record stances on related ideas, not on the minority's maps. Full methodology, dataset, and technical log are in `analysis/scripts/submission_search.py`, `data/submission_search_dataset.csv`, `findings/submission_search_findings.md`, and `findings/submission_search_log.md`.

Result: the commission majority's claim is partially refuted. Scored on the five places the majority's statement names, the claim holds for Airdrie, Cochrane (Calgary-Nolan Hill-Cochrane) and St. Albert, and is partly wrong for Chestermere and Red Deer (§5.9.4.1 table; C49). The framing throughout this section is objective and fact-based: the question is whether supporting submissions exist on the record, not whether the majority acted with any particular intent in characterising them.

Verdict by place (the five the majority named):

- **Partly wrong** (supporting submissions exist, matched or outnumbered by opposing ones):
- Chestermere separation: 3 supporters, 3 opposers, net 0, 23% of engaged submissions support
- Red Deer hybrids: 2 explicit supporters plus 3 aligned, 4 opposers; 9% of engaged submissions support explicitly (22% with aligned)
- **Holds** (support is negligible or zero):
- Airdrie 4-way: 0 supporters, 2 opposers, 0% of 4 engaged submissions
- Calgary-Nolan Hill-Cochrane: 0 submissions mention this configuration at all
- St. Albert-Sturgeon (minority variant): 0 clear supporters for the minority's alternative configuration; label-ambiguity caveat

Not named by the majority's statement. Two other minority configurations drew supporting submissions, reported separately because the majority's "no public support" statement does not name them: Rocky Mountain House-Banff Park (3 explicit supporters plus at least 4 aligned, 1 opposer; 15% explicit, 35% with aligned) and Olds-Three Hills-Didsbury as a rural unit (2 for, 2 against; 40%). An earlier tier list scored these two as refutations of the majority's claim, with counts taken from `findings/claim_significance_analysis.md` that differ from the table; both errors are corrected here.

The distinction matters because the majority's claim was an argument for procedural weight, not a technicality. Where it said "no public support" for the Airdrie 4-way split, it is

effectively correct — four engaged citizens discussed the configuration and none supported it.

Implication for the D2 procedural finding: the claim narrows but does not dissolve. The majority's statement held in three of the five places it names and was partly wrong in two. The audit reports this split rather than treating the statement as uniformly unsupported or uniformly sound. Readers on both sides of the debate have incentive to flatten the finding: critics will say "the majority was wrong" without the split, and defenders will say "most places held up" without naming the two that did not.

5.9.4.1 Evidence by configuration, with per-area proportions

For each configuration, we report submissions mentioning it, submissions supporting the minority direction, and submissions opposing. The "support rate" column is the ratio of explicit supporting submissions to total submissions engaging with the configuration — a local measure of public backing among engaged citizens, not a measure of province-wide support.

MINORITY CONFIGURATION	MENTIONS	SUPPORTING MINORITY	OPPOSING	NEUTRAL	SUPPORT RATE	VERDICT
Airdrie 4-way split	4	0	2	2	**0 / 4 = 0.0%**	Majority's claim stands
Calgary-Nolan Hill-Cochrane hybrid	0	0	0	0	**0 / 0 = n/a**	Majority's claim stands
Rocky Mountain House-Banff Park (s.15(2))	20	3 + ≥4 aligned	1	~15	**3 / 20 = 15%** (7 / 20 = 35% with aligned)	Not named in the claim; support exists
Olds-Three Hills-Didsbury rural unit	5	2	2	1	**2 / 5 = 40%**	Not named in the claim; support exists
Chestermere separation	13	3	3	7	**3 / 13 = 23%**	**Partially refuted**
Red Deer hybrids	23	2 explicit + 3 aligned	4	17	**2 / 23 = 9%** (5 / 23 = 22% with aligned)	**Partially refuted**
St. Albert-Sturgeon (minority alternative)	11	0 for minority variant (2 for majority name)	1	8	**0 / 11 = 0%** for minority alternative	Majority's claim stands

5.9.4.2 Direct quotation evidence

Rocky Mountain House-Banff Park — EBC-2025-2-0619 ("Appropriate Political Representation for Alpine Alberta"). Under "3.2 Proposed Electoral Division Amendment 2: Rocky Mountain House-Banff":

> *"The proposed Rocky Mountain House-Banff electoral district brings together the upper Bow and North Saskatchewan headwaters, adjacent mountain parks, surrounding Crown land, and the communities depending on these landscapes for their livelihoods. It would include Lake Louise, Saskatchewan River Crossing, Red Deer River Crossing, Nordegg…"*

This is a direct textual proposal for the minority's s.15(2)-invoking configuration by the submission's explicit name. The configuration the commission majority called a "bad faith effort" (the NP extension to the BC border, §5.1.4) is also the one with the *clearest public support* in the submissions, though the majority's "no public support" statement does not name it — a finding that tightens the tension in the audit rather than resolving it.

Rocky Mountain House-Banff Park — EBC-2025-2-0091 (Nordegg resident):

> *"I recommend riding boundaries include all of Clearwater County, including Rocky Mountain House, with other western communities like Sundre and Banff."*

Rocky Mountain House-Banff Park — EBC-2025-2-1029 (former Clearwater County Reeve): urges keeping Clearwater County together and linking it to the Banff park gateway. Directionally aligned with the minority configuration.

Olds-Three Hills-Didsbury — EBC-2025-2-0209 (Alan Balson, Beiseker):

> *"Keep Beiseker and the surrounding rural area in a reconstituted rural riding including Olds, Didsbury, Carstairs, Three Hills, and the agricultural areas around them."*

This proposal preserves the minority's rural ODH unit and opposes the majority's dissolution of it. A second submission from the same area (EBC-2025-2-0161, Councillor David Ledoyen) makes the same argument.

Red Deer hybrids — EBC-2025-2-0252 (Chad Krahn, Red Deer City Councillor):

"...a northern riding could encompass Sylvan Lake, Lacombe, and Blackfalds..."

A Red Deer elected official explicitly proposes a peri-Red-Deer hybrid structure functionally matching the minority's Red Deer-Blackfalds / Red Deer-Sylvan-Lacombe approach.

Chestermere — EBC-2025-2-0687, EBC-2025-2-0785, EBC-2025-2-0787 oppose Calgary-Chestermere merger, arguing Chestermere is a distinct municipality deserving its own representation. The minority moves southern Chestermere into Calgary-Peigan-Chestermere (final report p. 332); the majority keeps the city whole. These submissions support keeping Chestermere whole.

5.9.4.3 Proportional weight and impact on findings

The proportions matter because they tell us whether the public-input record produces *signal* or *noise* for each configuration. Three interpretive lines:

Sample-size caveat. For the Airdrie 4-way split and Nolan Hill-Cochrane configurations, engaged-submission counts are 4 and 0 respectively. These are small samples. The absence of supporting submissions in 4 mentions is consistent with "no public support" but doesn't exclude the possibility a larger sample would uncover some. For the other configurations, engagement is higher (5–23 mentions) and support-rate estimates are statistically more informative.

Support rates do not track engagement. Olds-Three Hills-Didsbury (40%, 5 mentions), Chestermere (23%, 13 mentions), and RMH-Banff Park (15% explicit, 35% with aligned; 20 mentions) show non-trivial alignment with the minority direction, but Red Deer, the most-mentioned configuration (23 mentions), has one of the lowest support rates. Of those three, only Chestermere is among the five places the majority's statement names, and there the statement is partly wrong. The pattern does not prove the minority configurations are correct — engaged citizens can be wrong.

The configurations with zero engaged support are also the ones with smallest sample sizes. Airdrie 4-way (0/4) and Nolan Hill-Cochrane (0/0) have the sharpest apparent rejection, but the sample sizes are too small for confident claims beyond "nobody in the engaged record asked for these." This is consistent with the majority's claim for those specific configurations but does not constitute a *refutation* of minority intent — it just means there is no recorded demand.

5.9.4.4 Impact on the majority's and minority's findings

For the majority report. The "no public support" framing (pp. 59 and 62) was a consequential argument. It implied the minority was advancing configurations against the clear weight of

public input. The evidence weakens it, partly, in two of the five places it names (Chestermere and Red Deer). The majority's substantive cartographic critique that the minority's hybrid choices fragment more communities (see §5.8.3, §5.8.4 of this audit) still holds; a compactness critique would not, since the between-map compactness direction reversed on the official boundaries (C2, C3). The *procedural* framing was partly overbroad.

For the minority report. The evidence helps the minority's procedural posture only modestly. Some configurations have documented support, which makes them harder for the majority to discount. The visible spatial concerns (§5.8.2: the RMH-Banff extension the majority objected to, Nolan Hill-Cochrane lasso, ODH capturing N Airdrie) and the structural population asymmetries (§5.1.1, §5.1.2, §5.1.3) are not affected by the public-support question. The minority cannot argue "our configurations reflect public demand" for Airdrie 4-way or Nolan Hill-Cochrane, where documented demand is absent.

For the audit's Section D procedural concern. The §5.9 critique narrows but does not disappear. The government's April 16 action transferred the remaining work to a legislature-selected committee and its advisory panel, which was not directed to start from either map. The public-support concern applies to whatever the panel's map keeps: it is strongest for configurations genuinely lacking public support (Airdrie 4-way, Nolan Hill-Cochrane) and weaker — though not absent — for configurations with some documented backing (RMH-Banff Park, Olds-ODH, Red Deer hybrids, Chestermere). An earlier framing of "the government adopted boundary choices nobody asked for" would overstate the record. The accurate framing is that a map drawn from either proposal would include a mixture, with some choices having no documented public support and others having it.

5.9.4.5 Limits of the verification

1. **About 93 submissions (6.9%) could not be machine-parsed** because their PDFs are image-only scans lacking a text layer or a detectable EBC-2025-X-NNN ID marker. OCR was out of scope. These could in principle contain additional supporting or opposing content not changing the refutation direction (which relies on identified supporting submissions) but could shift neutral / opposing counts.
2. **Keyword search precision.** Regex uses permissive co-occurrence windows (200–300 chars) and can miss submissions where the same configuration is described in paraphrased terms without the explicit place names used. Conversely, the Red Deer regex triggers on any Red Deer + {Blackfalds / Innisfail / Sylvan Lake / Lacombe} co-occurrence, which often simply describes the commission's *proposed* boundaries — those are neutrals, not supports.
3. **Position classifier is heuristic.** The code looks for support / oppose / against / recommend / should-not keywords near each match. Ambiguous classifications were manually reviewed and corrected in 13 cases (documented in `findings/submission_search_log.md`). CSV rows still reflect the automatic classification.

4. **Minority configuration names are the audit's labels, not the submissions'.** Citizens do not typically know the minority's precise labels (e.g., "Red Deer–Blackfalds"). A submission proposing a functionally equivalent configuration using different names is counted as directional support. The audit's rubric is generous on this point. The commission majority might not accept the same rubric.
5. **Attached sub-PDFs were not searched separately.** Some submissions reference external attachments (e.g., EBC-2025-1-0139 references "Airdrie-Feedback-Submission-AEBC-May-2025.pdf"). Only the enclosing batch PDF's text layer was searched. Additional evidence may reside in attachments.

The refutation finding is robust to limits (1)–(3) because it rests on identified counter-examples rather than exhaustive enumeration. Limits (4) and (5) could affect counts but not direction of the finding. A full Track-B OCR pass over the roughly 93 missing submissions would strengthen the audit's credibility if it were used in legal proceedings. It would not likely change the qualitative verdict.

5.9.4.6 Full-corpus LLM sentiment analysis and Hansard transcript review

The keyword-based analysis in §5.9.4.1–5.9.4.5 addresses whether supporting submissions *exist* for each configuration. A separate, more comprehensive pass was subsequently run to quantify the *distribution* of stances — not just presence of support, but the balance between opposition, support, and contextual engagement — across both the written-submission corpus and the public-hearing transcripts.

Method. Two LLM-based classification pipelines were run using Claude Sonnet via the Claude CLI:

- *Full-corpus submission scan* (`submission_sentiment_llm_full.py`): **1,254 unique submission IDs processed**, two more than the 1,252 parseable submissions counted in §5.9.4; the two counts come from different passes and the difference is not reconciled, but coverage is essentially complete (corrected 2026-06-12 per T1.7 R2 Ref #12 — the round-1 "182 of 1,252 (14.5%)" correction was itself wrong, derived from `findings/sentiment_analysis_completion_report.md`'s misreading of the progress CSV; the round-2 audit verified `data/outputs/submission_sentiment_llm_full_progress.csv` shows 1,254 unique submission IDs were processed during the 2026-05-09→10 pass; rows are emitted only for non-Unrelated stance classifications, so apparent "silence" in the output table is not evidence of unprocessed input). **Row-level reconciliation closed (T4.9-sentiment-recon, 2026-06-12).** The progress CSV has 1,272 parsed rows (some duplicates) across 1,254 unique submission IDs. The results CSV has 827 parsed rows across three scan types: **388 full_corpus + 209 hansard_r1 + 230 hansard_r2 = 827** (round-1 of this reconciliation reported "271/85/96 = 452" — those numbers were back-fitted to the headline "452 deduplicated" figure but do not match the canonical results CSV row counts). The 452 deduplicated set is a downstream aggregation that drops Unrelated

stances and applies de-duplication of single-submission-multiple-configurations rows; that derivation is preserved in `findings/sentiment_analysis_completion_report.md` but the raw counts above are the source-of-truth. Published intensity-summary aggregates (`data/outputs/intensity_summary_table.csv`, 7 configurations) reflect the 452-deduplicated subset; values cited in §5.9.4.6 narrative are reconciled to that source. The "Red Deer −154 / Nolan Hill −122" aggregates that appeared in earlier drafts derive from a pre-deduplication scoring pass and have been replaced by the canonical −64 / −55 values from the deduplicated table.

- *Hansard transcript scan* (`hansard_sentiment_llm.py`): two rounds of EBC public-hearing Hansard transcripts (r1: May 2025 hearings, 2,773 KB; r2: January 2026 hearings, 2,675 KB) were parsed into community-participant turns. Turns mentioning configuration keywords were classified using the same seven-configuration schema. 3,107 community turns in r1 (209 classified rows in the results file); 2,358 in r2 (230). No hearing or submission could address the minority's maps: r1 predates even the interim report, and r2 (January 12–21, 2026) and the written submissions (closed December 19, 2025) predate the minority's late-January departure from the interim map. The counts record stances on related ideas, not on the minority's maps.

Both pipelines resume from a progress file, and their outputs are archived. The classifications are not bit-reproducible: the calls name an unpinned model alias and set no seed or temperature. Output: `data/outputs/submission_sentiment_llm_full_results.csv`.

Results — written submissions. 388 configuration-stance rows (271 of them non-neutral) across 292 unique submissions (from the 1,252-submission corpus). Overall: 189 Active Opposition (49%), 82 Active Support (21%), 117 Neutral/Contextual (30%).

CONFIGURATION	TOTAL ROWS	OPPOSITION	SUPPORT	OPP%	SUP%
Rocky Mountain House–Banff Park hybrid	104	56	37	54%	36%
Red Deer hybrid ridings	98	52	8	53%	8%
St. Albert merging with Sturgeon County	46	14	15	30%	33%
Calgary–Nolan Hill–Cochrane hybrid	43	25	5	58%	12%
Airdrie 4-way split	42	18	6	43%	14%
Olds–Three Hills–Didsbury rural unit	28	9	7	32%	25%
Chestermere merging with Calgary	27	15	4	56%	15%

Results — Hansard hearings. *439 relevant community turns classified across both rounds. Overall: 97 Active Opposition (22%), 91 Active Support (21%), 251 Neutral/Contextual (57%).*

CONFIGURATION	HANSARD TURNS	OPP%	SUP%	NET
Rocky Mountain House–Banff Park hybrid	112	22%	34%	+13 support
Red Deer hybrid ridings	75	8%	21%	+10 support
Airdrie 4-way split	74	27%	8%	+14 opposition

CONFIGURATION	HANSARD TURNS	OPP%	SUP%	NET
Calgary–Nolan Hill–Cochrane hybrid	55	24%	13%	+6 opposition
St. Albert merging with Sturgeon County	48	29%	25%	balanced
Olds–Three Hills–Didsbury rural unit	38	8%	21%	+5 support
Chestermere merging with Calgary	37	43%	11%	+12 opposition

Channel divergence. *The two measurement channels produce materially different signals on two configurations. Rocky Mountain House–Banff Park and Red Deer hybrids both show net opposition in written submissions (−19 and −44 respectively) but net support in Hansard hearings (+13 and +10). Airdrie, Calgary–Nolan Hill, and Chestermere are opposed in both channels, and St. Albert–Sturgeon is balanced in both. Olds–Three Hills–Didsbury is near-balanced in writing (net −2) and leans supportive in the hearings (+5).*

Weighted net-sentiment ranking (LLM-scored intensity). A second LLM pass (Claude Haiku, structured JSON output) scored each Active Opposition/Support row on a 1–3 intensity scale: 1 = mentioned in passing, 2 = clear position among several substantive points, 3 = primary focus or emphatic language (demanding, urging, calling the configuration unacceptable). Intensity-weighted net = sum of support intensity values minus sum of opposition intensity values, ranked across all channels:

CONFIGURATION	INTENSITY-WEIGHTED NET	DIRECTION
Red Deer hybrids	−64	Channel divergence
Airdrie 4-way split	−61	Opposed, both channels
Calgary–Nolan Hill–Cochrane	−55	Opposed, all channels
Chestermere merging with Calgary	−47	Opposed, both channels
Rocky Mountain House–Banff Park	−9	Channel divergence
St. Albert–Sturgeon County	−1	Near-balanced overall
Olds–Three Hills–Didsbury	+6	Net supported

Note: LLM intensity scoring completed across 452 rows in `data/outputs/sentiment_intensity_scores.csv` (corrected 2026-06-13 per T1.7 R2 S22): 263 full-corpus AO/AS rows (from the 1,252 written submissions — 271 in the raw results CSV, 8 excluded in the deduplication/scoring pass); 85 Hansard-r1 turns; 103 Hansard-r2 turns; 1 blank/unscored row. N/C and Unrelated rows not scored. Earlier draft cited 271/85/96 = 452 — the 271 was the pre-dedup full-corpus count and the 96 for hansard_r2 was wrong; canonical values above are from `sentiment_intensity_scores.csv` directly. Two configurations show pronounced channel divergence: Red Deer and Rocky Mountain House–Banff Park both exhibit strong opposition in written submissions but net support in Hansard hearings, consistent with differential-mobilization and participation-cost explanations discussed below.

The channel-divergence hypothesis. The divergence between written and in-person channels on RMH–Banff Park and Red Deer hybrids warrants a methodological note. One credible explanation is differential mobilization: written submissions are submitted asynchronously and may over-represent organized opposition groups or residents with strong objections, while in-person public hearings attract a broader cross-section including residents who favor local representation arguments but lack the organizational impetus to submit formally. This pattern — where written channels show stronger opposition than in-person channels on the same question — is documented in planning and zoning literature (Fischel 2001) though not specifically in electoral redistricting contexts.

A second explanation specific to the RMH–Banff Park configuration is geography: citizens from Nordegg, Rocky Mountain House, and the Jasper/Banff corridor who would benefit from a unified mountain constituency may be more likely to attend regional in-person hearings (which were held in part in those communities) than to submit written comments. This is not a partisan-sorting argument but a participation-cost argument — travel to a hearing is a sunk cost filtering for engagement intensity, not partisan direction.

The audit does not assert either explanation as established. The finding is: two channels produced divergent signals on two specific configurations, the divergence is large enough to be substantive (net flips from −44 to +10 rows for Red Deer, and from −19 to +13 for Rocky Mountain House–Banff Park), and commissioners who weighted in-person testimony more heavily — as is common in **polycentric advisory** administrative proceedings (corrected 2026-06-12 per T1.7 Referee #12; boundary commissions are not "quasi-judicial" — they make polycentric policy recommendations, not adjudicative decisions) — would have received a materially different impression of public sentiment on those configurations than commissioners who weighted the written record equally. Whether the weighting is appropriate is a procedural-design question outside the scope of this audit.

Relationship to §5.9.4.1–5.9.4.4. The LLM full-corpus pass confirms and sharpens the keyword-based findings from §5.9.4. The commission majority's "no public support" claim is most defensible for Airdrie (43% opposition, 14% support in submissions; 27% vs 8% in Hansard — consistently opposed in both channels) and least defensible, among the places it names, for St. Albert–Sturgeon (balanced in both). RMH–Banff Park (36% support in submissions, 34% in Hansard) drew the most support but is not among the places the claim names. The LLM pass addresses limits (2) and (3) from §5.9.4.5 by replacing keyword matching and heuristic classification with direct machine-reading of full submission text.

5.9.4.7 Rationale–submission alignment cross-reference

This section maps the combined sentiment corpus (§5.9.4.6) to the minority's published rationales. Of 25 rationales recorded in `data/outputs/minority_rationales.csv`, six could be matched to a sentiment configuration. The other 19 cover Edmonton-area, rural, and procedural rationales for which no submission configuration data exist.

Method. For each matched rationale, rows were counted by classification (Active Opposition / Active Support / Neutral/Contextual). Taking-sides percentages exclude Neutral/Contextual rows. Three alignment labels are used:

- **CONTRA_RATIONALE** (called CONTRA_COMMISSION in earlier drafts; the rationales are the minority's, not the commission's) — the audit's verdict on the minority's rationale was "SUPPORTS" or "PARTIALLY SUPPORTS", but the combined record is majority-opposing.
- **ALIGNS_WITH_AUDIT** — the audit's verdict was skeptical (INCONCLUSIVE or FAIL), and the submission record is also majority-opposing.

- **CONTRA_AUDIT** — the audit flagged a test failure, but the submission record leans toward support.

All counts use the same LLM classifications as §5.9.4.6. Human inter-rater reliability scoring on a 60-item sample is pending.

RATIONALE	CONFIGURATION	AUDIT VERDICT	OPPOSING	SUPPORTING	ALIGNMENT
R1	Calgary-Nolan Hill-Cochrane	PARTIALLY SUPPORTS	38 / 50 (76%)	12 / 50 (24%)	CONTRA_RATIONALE
R2	Calgary-Peigan-Chestermere	LEANS CONTRADICTS (2021 Census 98-10-0459: 86.0% of Chestermere out-commuters → Calgary CY; specific SE-Calgary/Forest-Lawn pairing unsupported)	31 / 39 (80%)	8 / 39 (20%)	ALIGNS_WITH_AUDIT
R3	Calgary-Airdrie	SUPPORTS	38 / 50 (76%)	12 / 50 (24%)	CONTRA_RATIONALE
R10	Red Deer-Lacombe	PARTIALLY SUPPORTS	58 / 82 (71%)	24 / 82 (29%)	CONTRA_RATIONALE
R12	Rocky Mountain House-Banff Park	PARTIALLY SUPPORTS (hist.); CLOSED-FAIL (area)	81 / 156 (52%)	75 / 156 (48%)	ALIGNS_WITH_AUDIT
R13	Olds-Three Hills-Didsbury	PARTIALLY SUPPORTS; CLOSED-FAIL (Airdrie slice)	12 / 27 (44%)	15 / 27 (56%)	CONTRA_AUDIT

Fractions are taking-sides only. Combined corpus: written submissions + Hansard r1 + Hansard r2. Total rows per rationale: R1 = 98, R2 = 64, R3 = 116, R10 = 173, R12 = 216, R13 = 66.

Findings. Three rationales (R1, R3, R10) are CONTRA_RATIONALE: the minority cited community-of-interest grounds the audit had rated as supported or partly supported, but the combined record runs 71–76% opposing among those who took a position. Two (R2, R12) are ALIGNS_WITH_AUDIT: the audit's verdict was uncertain or test-failing, and submissions are also majority-opposing or near-split. One (R13) is CONTRA_AUDIT: the audit flagged a population-arithmetic failure on the Airdrie slice, and submissions lean 56% toward support, but the supporting rows do not bear on that failure. The classifier labelled the configuration "extending to Airdrie"; every supporting row backs keeping or restoring the rural Olds–Didsbury–Three Hills unit, and none endorses extending it into Airdrie.

Channel-divergence note for R12. The 52 / 48 combined split on RMH–Banff Park masks the divergence from §5.9.4.6: written submissions are 54% opposing, while Hansard in-person testimony is net-supportive. A commission weighting in-person testimony more heavily would have seen a different picture. No such divergence exists for R1 or R3, which are majority-opposing in both channels; R10 (Red Deer) diverges like R12.

Interpretation. CONTRA_RATIONALE findings do not prove improper conduct. The minority commissioners may rely on evidence beyond the archived record, and their rationales cite community-of-interest ties rather than public endorsement. The finding is that the publicly verifiable consultation record leans against three of the five rationales the audit had rated as supported or partly supported (R1, R3, R10, R12, R13). No submission could respond to the minority's maps themselves (§5.9.4).

5.9.5 Constitutional backdrop

Reference re Provincial Electoral Boundaries (Saskatchewan), [1991] 2 SCR 158, established Canadian electoral redistribution is measured against an "effective representation" standard, not strict population parity. Within the standard, deviations from provincial average are permissible when they serve recognized factors (geography, community of interest, minority representation). An audit finding (a) directionally-consistent partisan asymmetry in a proposal and (b) a process that set both commission proposals aside would be evaluated against *Saskatchewan Reference* if challenged — but this audit does not assess the constitutional question. It provides the evidentiary basis for others to do so.

Application to specific boundary disputes. *Raîche v. Canada (Attorney General)*, 2004 FC 679, applies the Saskatchewan Reference standard to a specific boundary dispute without producing a bright-line ceiling on partisan-asymmetric outcomes. *Raîche* turned on statutory grounds (community of interest under the federal Act), found no s.3 violation, and did not address partisan asymmetry (§2). The audit's findings — directional partisan asymmetry, the §15(2) extension the commission majority objected to, cities divided into more districts than their size requires, and procedural departure from independent-commission practice — are the kinds of evidence a court applying the effective-representation standard might weigh.

The 2026 Quebec ruling. The constitutional landscape shifted materially on April 22, 2026, six days after Government Motion 37 was introduced (April 16) and one day after it passed (April 21), creating the Lunty committee. The Supreme Court of Canada dismissed Quebec's appeal of a Quebec Court of Appeal decision striking down the Legault government's 2024 statute blocking Quebec's *Commission de la représentation électorale* from redrawing the provincial map (the redrawing eliminated one Gaspé Peninsula riding and one Montreal east-end riding in favour of two new districts in the Laurentians/Lanaudière and Centre-du-Québec regions). The SCC ruled 7–2 at the hearing, with reasons to follow (*Lalande*, ¶1). The QCA ruling the SCC upheld held the freeze law violated sections of the Charter guaranteeing democratic representation by allowing significant disparities in voter weight to persist. Reported in CBC News, "Quebec's redrawn electoral map will stay after Supreme Court ruling" (2026-04-22) and Canadian Press / CTV News, "Supreme Court rejects Quebec's attempt to block changes to election map boundaries" (2026-04-22). The Supreme Court's reasons followed on May 1, 2026: *Quebec (Attorney General) v. Lalande*, 2026 SCC 13 (Kasirer J.; Côté and Rowe JJ. dissenting; archived at `evidence/law/lalande_2026scc13_lexum.html`). The s.3 infringement found at first

instance was not appealed, so the appeal turned on s.1 alone (¶2). The law failed minimal impairment, and its unanimous passage did not save it (¶¶7–9). On June 12, 2026 Quebec's National Assembly passed its own 127-seat map.

Doctrinal implications for Alberta. Three relevant doctrinal observations, from the reasons in *Quebec (AG) v. Lalande*, 2026 SCC 13:

1. **A legislature that halts an independent commission's redistribution to protect a region must show the halt goes no further than that protection needs.** The majority accepted preserving the electoral division in Gaspésie as a pressing and substantial objective (¶3). It rejected the broader objective the Attorney General pleaded, the protection of "regions undergoing devitalization", as too imprecise for the *Oakes* analysis and not rationally connected to halting the whole map (¶¶4–5). The law failed at minimal impairment: the legislature could instead have enacted "a law temporarily protecting the electoral divisions in Gaspésie while leaving the Commission to complete its work for the rest of Quebec" (¶8). The CAQ government's stated rationale — protection of Gaspé and other rural ridings — was the same class of argument the Alberta minority commissioners advance in Appendix E p. 302: "Hybrid constituencies are not only a good reflection of Alberta, but also the best available instrument for preserving rural and suburban representation in the face of sustained urban growth" (R17). A 2026-06-12 correction removed the last six words on the ground that they were not in the archived rationale (`data/outputs/minority_rationales.csv`, which truncates the sentence); they are in the final report, and the full sentence is restored. Both are rural-preservation justifications offered against statutory parity. The Court did not reject regional protection as an objective; it rejected a province-wide halt as broader than that objective needed. A hypothetical Alberta statute reassigning commission-recommended boundaries on the same grounds would face the same question: whether a narrower measure would have served the objective.
2. **The Court was divided, and the majority did not rest on *Saskatchewan Reference* [1991].** The majority's reasons cite *Oakes*, *K.R.J.*, *Hutterian Brethren* and *RJR-MacDonald*, not *Saskatchewan Reference*. Côté and Rowe JJ., relying on it, would have upheld the law; in their view neither the 25 percent threshold nor an independent process is a constitutional requirement (¶14).
3. **Charter section 3 is the operative provision.** Both the QCA and the SCC framed the analysis as a Charter-rights question, not a separation-of-powers question. This matters for any Alberta challenge: a section 3 challenger would have standing as an affected voter, not just as a constitutional litigant.

What this means for the audit's procedural critique. The April 16 Alberta motion — reassigning the remaining redistricting work to a UCP-majority legislative committee and its advisory panel partway through the cycle — operates under a constitutional landscape which, six days later, became significantly less hospitable to legislative reassignment of independent commission-recommended boundaries. The audit's framing in §5.9.3 (Alberta's 1992 select

committee of MLAs also drew the map in the commission's place; what distinguishes 2026 is narrower: the commission produced a majority report, which s.9 of the Act makes the commission's report, and it was set aside) now extends to a substantive constitutional question no longer hypothetical: the SCC has just upheld the striking down of a parallel Quebec law as broader than its accepted objective needed (¶¶8–9). Whether the Alberta situation is constitutionally distinguishable — for instance, because the Lunty committee is structured differently from a legislative-freeze law, or because Alberta's voter-weight situation differs materially from Quebec's — is for a court to decide on its own facts. The audit's positive contribution is to surface the structural-asymmetry evidence (§5.4–§5.8) any such challenge would draw on.

5.9.6 Evidence trail for the six contested-rationale checks

Earlier versions of the public report said "five of six of the minority's published reasons fail under check". This subsection consolidates the evidence base for each of the six claims so a journalist, a counsel of record, or a hostile peer reviewer can trace each line back to a primary source — or, where the trail is incomplete, see the gap. The six are claims in the public summary, checked against the minority's rationales in Appendix E (pp. 285–362) of the 2025–26 EBC final report; they are not six rationales the minority itself singled out, and two of them (Claims 1 and 7) have no per-district minority rationale behind them. Recounted after the corrections below, two of the six fail on population arithmetic (Claims 1 and 4), two are partly supported (Claims 2 and 6), one was not tested on its stated grounds (Claim 3) and one is withdrawn (Claim 7).

Registration status. The rationale-failure check is a qualitative post-hoc audit, not a pre-registered test. Of the nine OSF registrations associated with this paper (w2s8k, r3zm7, qsgy8, 6pt83, 9wp5y, yvc7g, s58a6, he53s, u47bq), only 9wp5y names a rationale-validity test, scoring each of the minority's 25 inventoried justifications as pass, fail or partial; it was filed after this check had been computed (April 22, 2026). None names a cleaner-alternative check. The finding should be read as qualitative context for the structural pattern first recorded in the repository in April 2026, after the values were computed (§5.5), not as an additional pre-registered measurement. A reader who weights only pre-registered findings should disregard this rationale summary and rely solely on the structural metrics in §5.4–§5.8.

A general note on the strength bands used below. **Strongly supported** means the verdict rests on a downloaded primary dataset any reader can re-run with the published code. The rationale is contradicted on the dataset's own face. **Moderately supported** means the verdict rests on a documented public source (statute, government boundary map, commission text) any reader can re-verify, but the comparison the audit performs adds an inferential step. **Weakly supported** means the audit asserts a fact consistent with general knowledge but not separately documented in the audit's own files. A careful reader would have to take the assertion on the audit's word until the underlying check is filed. **Currently unsupported** means the public-facing summary phrases a check the audit's own evidence

files do not document. The line should not appear in legal-grade or journalistic-grade citation without follow-up work.

Claim 1: The four Airdrie quadrants are within 8% of each other on every demographic measure the commission considers.

- *Source the minority cites in their published rationale*: Appendix E, p. 339 (R14, "Airdrie East") and the inventory's R3/R4/R18 growth-projection cluster. The minority does not, in fact, give a per-quadrant demographic-difference rationale in the published text; an earlier draft of the public report attributed the per-quadrant rural/urban-character argument to the minority commissioners as the implied basis for the four-way split. The minority's *explicit* rationale is growth and commuter-tie, not demographic heterogeneity.
- *Evidence the audit checked it against*: `findings/justification_tests_findings.md` Test 3, using `data/outputs/justification_test_inputs.csv` (StatCan 2021 Census, City of Airdrie CSD 4806021, total pop 74,100). The test compares the population arithmetic of the 4-way split against a 2-way alternative.
- *What the data shows*: The arithmetic shows a 2-way split is sufficient — each half ≈37,050, requiring only ~4,147 additional non-Airdrie residents to clear the 41,197 statutory floor. The minority's split is uneven, not four quarters: Airdrie-East keeps 54.7% of the city and is 89.6% Airdrie; Calgary-Airdrie (24.0% of the city) and Calgary-Foothills-Airdrie West (20.9%) are Calgary-majority hybrids; Olds-Three Hills-Didsbury takes under 1% (2021 census areas; `data/outputs/airdrie_split_shares_2026-10-31.json`). The "within 8% on every demographic measure" line in an earlier draft of the public report is **not directly documented in the audit's evidence files**: no per-quadrant demographic-comparison table (median income, age structure, dwelling type, immigration share, language) for the four minority Airdrie carves exists in `analysis/`, `data/`, or `analysis/methodology/`.
- *Verdict*: **Inconclusive on the line as written; Fail on the broader rationale.** The minority's split is unforced by population arithmetic (which the audit documents) but the specific "within 8% of each other on every demographic measure" sentence is a stronger claim than the existing files substantiate.
- *Documentation file*: `findings/justification_tests_findings.md` (Test 3); `data/outputs/justification_test_inputs.csv`.
- *Reproducibility*: `python analysis/scripts/justification_tests.py`. A reader can re-run the population test independently. The "8% demographic" sub-claim cannot be reproduced from the existing files and requires per-quadrant census tabulation as follow-up.

Claim 2: Cochrane's most common commuter destination is Cochrane itself. Among out-of-town commuters, Calgary-Centre is named more often than Foothills.

- *Source the minority cites in their published rationale*: Appendix E, p. 331 (R1): "residents move fluidly between jurisdictions for work, education, health care, and commerce." The minority frames the Calgary-Nolan Hill-Cochrane lasso as a commuter-tie district pairing Cochrane with the Nolan Hill / Sage Hill ward of NW Calgary specifically.
- *Evidence the audit checked it against*: Statistics Canada 2021 Census, table 98-10-0459-01 ("Commuting flow from geography of residence to geography of work by gender: Census subdivisions"), filtered to Cochrane CSD origin (DGUID `2021A00054806019`). Methodology in `analysis/methodology/reference/cochrane_journey_to_work.md`. Output in `data/outputs/cochrane_journey_to_work.csv`.
- *What the data shows*: Of 8,550 Cochrane-resident workers with a usual place of work, **4,205 (49.2%) work within Cochrane itself**, **3,065 (35.8%) commute to Calgary CY**, 345 (4.0%) to Rocky View County, 185 (2.2%) to Canmore. The 49.2% within-Cochrane share is the largest single destination by a wide margin. The "Calgary-Centre named more often than Foothills" sub-claim in the public summary is a **stronger statement than the table can support**: the public Census table publishes commute destinations at CSD granularity (Calgary CY as a single unit), not at electoral-district or ward granularity. Within-Calgary disaggregation is not in the public release. The methodology file flags this explicitly: the rationale is unevidenced at sub-CSD resolution rather than falsified.
- *Verdict*: **Partial support.** R1 says residents "move fluidly" between jurisdictions; it does not claim Calgary is the primary destination. Calgary is the largest out-of-town destination (35.8%), which partly supports the tie, while the largest single flow stays within Cochrane (49.2%), matching §5.8.5's "partial support". The within-Calgary sub-claim ("Calgary-Centre named more often than Foothills") is not testable in CSD data and is no longer in `report_public.md`.
- *Documentation file*: `analysis/methodology/reference/cochrane_journey_to_work.md`; `analysis/methodology/reference/minority_rationales_validation.md` §R1; `data/outputs/cochrane_journey_to_work.csv`.
- *Reproducibility*: StatsCan table 98-10-0459 is publicly downloadable at `https://www150.statcan.gc.ca/n1/tbl/csv/98100459-eng.zip`; the filter on DGUID `2021A00054806019` and the per-destination ranking are scripted in the methodology file. A reader can re-run end-to-end.

Claim 3: The Rocky Mountain House-Banff Park extension into Banff National Park has no agricultural land base ("ranching community of interest") it can refer to.

- *Source the minority cites in their published rationale*: Appendix E, p. 352 (R12). The minority invokes the s.15(2) exception for the Banff National Park extension on four grounds: north-south economic corridor along Highway 22; Rocky Mountain House as a hub for Clearwater County; division of regional Indian reserves from the nearest economic hub; and historical precedent of Banff NP portions in a west-central electoral division. For the s.15(2) exemption itself it cites the district's "geographic size, location

on a provincial border, and small communities" (pp. 351–352). The phrase "ranching community of interest", attributed to the minority in earlier drafts, is the audit's own gloss (`banff_extension_population_check.md`); the minority does not use it.

- *Evidence the audit checked it against:* `findings/justification_tests_findings.md` Test 2 (area arithmetic), §5.1.4 + §5.3.3 of this report (engineered-boundary signature E1–E3), and `analysis/methodology/reference/banff_extension_population_check.md` (polygon-clipped DA population pull on the Banff extension portion). The 2019 predecessor area (Bill 33 shapefile attribute `Km2`) is 24,468 km², already 22 % above the s.15(2)(a) 20,000 km² threshold without the NP extension. The minority's own population figure for the extended district is 38,298 (−30.3 %), still outside the ±25 % band even with the extension.
- *What the data shows*: The NP extension is **not load-bearing for either area or population qualification** under s.15(2). On the population side, the polygon-clipped 2021-Census-DA pull at `analysis/methodology/reference/banff_extension_population_check.md` finds **approximately 491 area-weighted residents** inside the extension polygon (not zero) — concentrated in the Lake Louise / Saskatchewan River Crossing / Nordegg corridor visitors-services area-weighted aggregation. The earlier "zero year-round residents" framing was an oversimplification of an inhabited-but-very-sparse polygon. On the agricultural side, the *Canada National Parks Act* (S.C. 2000, c. 32) statutorily prohibits agricultural tenure on national-park land, so a "no working ranches inside the park-land slice" finding is statutorily entailed for the in-park portion but **not separately verified** for adjacent Crown-land grazing-lease territory the extended district also touches. A ranching community of interest (the audit's gloss) would therefore have no agricultural land base *inside the park slice*, but the audit does not file a check on grazing-lease territory adjacent to it.
- *Verdict:* **Not tested on its stated grounds; not counted as a fail.** The extension is not needed for s.15(2) qualification on area (documented): the district meets four of five criteria without it. The minority does not claim the extension is needed, and its four stated grounds (Highway 22 corridor, Rocky Mountain House as a hub, keeping reserves with their economic hub, historical precedent) were not tested against data. The "ranching community of interest" verdict in earlier drafts tested the audit's own phrase and is withdrawn. The previous public-facing precision ("zero residents, zero ranches") was overstated and has been corrected in `report_public.md`.
- *Documentation file*: `findings/justification_tests_findings.md` (Test 2); §5.1.4, §5.3.3 of this report; `analysis/methodology/reference/minority_rationales_validation.md` §R12; `analysis/methodology/reference/banff_extension_population_check.md`.
- *Reproducibility*: The area arithmetic is reproducible from the 2019 Bill 33 shapefile (`data/shapefiles/reference/alberta_2019_eds/EDS_ENACTED_BILL33_15DEC2017.shp`). The polygon-clipped population pull (~491 area-weighted residents) is reproducible from

the methodology file's documented DA-intersection pipeline. The grazing-lease check on adjacent Crown land remains future work.

Claim 4: North Airdrie is suburban. Olds and Didsbury are rural service centres.

- *Source the minority cites in their published rationale*: Appendix E, p. 349 (R13): "extending the boundaries of the existing Olds-Didsbury-Three Hills south to include more portions of Rocky View County... keep established communities of interest together along the Highway 2 corridor between Red Deer and Airdrie." The minority frames the southern extension as community-of-interest continuity along Highway 2.
- *Evidence the audit checked it against*: `findings/justification_tests_findings.md` Test 1 (population arithmetic of the rural Olds/Didsbury/Three Hills/Mountain View/Kneehill core sums to 43,691 — already above the 41,197 floor without any Airdrie territory). `analysis/methodology/reference/minority_rationales_validation.md` §R13 cross-checks the Highway-2 continuity claim against the 2019 enacted Olds-Didsbury-Three Hills district (which already contains Olds, Didsbury, Carstairs, Three Hills, Crossfield without the Airdrie slice).
- *What the data shows*: The arithmetic shows the Airdrie slice is unforced. The "North Airdrie is suburban; Olds and Didsbury are rural service centres" sub-claim is a **descriptive characterization broadly defensible from public sources** (City of Airdrie 2024 Growth Report describes Airdrie as a Calgary-CMA satellite city; the Town of Olds 2024 municipal profile and Town of Didsbury directory describe both as agricultural-services hubs in Mountain View County). The validation file's verdict on R13 is "PARTIALLY SUPPORTS" the continuity-along-Hwy-2 framing while flagging the Airdrie slice as CLOSED-FAIL on population math, not on demographic mismatch. Note: an earlier draft of `report_public.md` contained the phrase "Census-of-agriculture data says" (approximately line 198); that phrase has since been removed and the current public report does not assert a Census of Agriculture comparison. No Census of Agriculture extraction for North Airdrie / Olds / Didsbury exists in `analysis/` or `data/`; no such claim appears in the current published version.
- *Verdict*: **Fail on population necessity (documented); Weakly supported on the suburban-vs-rural-service-centre characterization (descriptively true but not separately filed).** The public summary has been corrected to reflect what the audit actually documents.
- *Documentation file*: `findings/justification_tests_findings.md` (Test 1); `analysis/methodology/reference/minority_rationales_validation.md` §R13.
- *Reproducibility*: The population arithmetic is reproducible end-to-end. The suburban-vs-rural-service-centre demographic comparison would require StatCan Census Profile dissemination-area extraction for the relevant CSDs plus a Census of Agriculture pull; neither is currently scripted.

Claim 6: The shared school division (Red Deer-Sylvan Lake) contains 8% of Red Deer's school-aged population.

- *Source the minority cites in their published rationale*: Appendix E, p. 351 (R11): "By placing rural populations in the same electoral division as urban communities in the Hwy 2 corridor, it is possible to achieve effective representation and overcome challenges with dividing communities of interest existing in previous electoral divisions" — including a "go to school" reference invoked alongside the urban-rural pairing.
- *Evidence the audit checked it against*: Alberta Education school-authority boundary maps (`https://www.alberta.ca/alberta-school-division-maps`) cross-referenced in `analysis/methodology/reference/school_division_coherence.md` and `analysis/methodology/reference/minority_rationales_validation.md` §R11. Sylvan Lake CSD (pop 15,995) is in **Chinook's Edge School Division No. 73** for public schools; the City of Red Deer (pop 100,844) is served by **Red Deer Public Schools**; **Red Deer Catholic Regional Schools** serves both Red Deer and Sylvan Lake. R11 does not claim a shared school division; it says rural residents "go to school" in the urban communities, and through the Catholic division some do. **Commuter tie (added 2026-06-13):** StatsCan 98-10-0459 origin-CSD data for Sylvan Lake (`data/outputs/sylvan_lake_journey_to_work.csv`) confirms 54.4% of Sylvan Lake out-commuters (1,520 of 2,795) work in the City of Red Deer — the dominant non-local destination. The "where they work" portion of R11 is **supported** at CSD level; the "go to school" portion is partly supported.
- *What the data shows*: The red-team file (`analysis/methodology/red_team_consolidated.md`, PUB-20) cites about 375 Sylvan Lake students bused to Red Deer Catholic schools, from sources not yet filed in the manifest. The "8% of Red Deer's school-aged population" line in an earlier `report_public.md` is **not documented in the audit's files**: no file extracts Red Deer's 5–17 population from StatCan or Alberta Education enrolment records. The school-coherence file's verdict ("CONTRADICTS — different divisions") considered public divisions only.
- *Verdict*: **Partly supported.** The work tie is supported and the school tie partly supported; the earlier "Fail" rested on public divisions alone and on an undocumented 8% figure.
- *Documentation file*: `analysis/methodology/reference/school_division_coherence.md`; `analysis/methodology/reference/minority_rationales_validation.md` §R11; `analysis/methodology/reference/sylvan_lake_innisfail_journey_to_work.md`; `data/outputs/sylvan_lake_journey_to_work.csv`.
- *Reproducibility*: The qualitative division-mismatch is reproducible from Alberta Education's published boundary map. The commuter flow is reproducible via `analysis/scripts/fetch_journey_to_work_csds.py` against StatsCan 98-10-0459. The 8% magnitude requires Red Deer 5–17 population + Chinook's Edge enrolment served from Red Deer city neighbourhoods; neither is currently scripted. **Public-facing language should read: "Sylvan Lake and Red Deer have different public school divisions; one Catholic division serves both."**

Claim 7: For St. Albert-Sturgeon, the majority map and the minority map independently arrive at the same two-district structure under the Act's constraints — when two independent drafting teams converge, the configuration is constraint-forced rather than engineered. (Withdrawn; see the verdict.)

- *Source the minority cites in their published rationale*: The minority's St. Albert-Sturgeon configuration appears in the inventory (`analysis/methodology/reference/school_division_coherence.md` §St. Albert-area hybrid) but **does not have a per-district published rationale in the R1–R18 inventory** (`analysis/methodology/reference/minority_rationales_inventory.md`). The audit's "Stands" verdict is therefore not a direct test of the minority's stated reason; it is an *audit-internal verdict based on a convergence test*: where two independent drafting teams (the three majority commissioners and the two minority commissioners) reach the same configuration under the same constraints, the configuration is treated as constraint-forced rather than designed.
- *Evidence the audit checked it against*: Earlier drafts read the §5.6 city-wide split table as showing St. Albert at "1 ED" on both maps. That table now reads 2 EDs (majority) and 3 EDs (minority) after C12, and the spatial overlay in `data/municipal_splits.json` shows the minority dividing the city three ways (2→3). `analysis/methodology/reference/school_division_coherence.md` documents St. Albert Public Schools serves only the City of St. Albert; Sturgeon Public Schools serves Morinville, Legal, Gibbons, and Sturgeon County. The City of St. Albert (2021 census 68,232) is below the 68,661 ceiling but above the 41,197 floor, so it could in principle stand alone — but its commute and service geography binds it tightly to the Edmonton-corridor districts on its south boundary. `findings/claim_significance_analysis.md` row 7 documents no engaged citizen submission proposes a clearly distinct minority alternative for St. Albert-Sturgeon (0 supporters for the minority variant, 2 supporters for the majority's St. Albert-Sturgeon name — label-ambiguity caveat noted).
- *What the data shows*: The two maps do not converge on the official boundaries: the majority divides St. Albert in two, the minority in three. The two sides were also not independent drafting teams; they were one commission working from a unanimous interim map. The earlier "no other configuration satisfies both the community-of-interest and the ±25% rule simultaneously" framing was a counterfactual non-existence claim the audit could not prove, and the convergence framing that replaced it does not hold either.
- *Verdict*: **Withdrawn.** The convergence premise fails, and the minority gives no per-district rationale to test, so the configuration is not scored.
- *Documentation file*: §5.6 (city-wide split table — St. Albert row); `analysis/methodology/reference/school_division_coherence.md`; `findings/claim_significance_analysis.md` row 7; `analysis/methodology/reference/minority_rationales_validation.md` (St. Albert-Sturgeon not separately listed).

- *Reproducibility*: The split counts are reproducible from `analysis/scripts/municipal_splits.py` (`data/municipal_splits.json`).

Strength-banding summary across the six claims (claims keep their earlier numbering; there is no Claim 5).

#	CLAIM SHORT FORM	VERDICT IN PUBLIC SUMMARY	STRONGEST EVIDENCE BAND ACTUALLY FILED	SUB-CLAIM NOTES
1	Airdrie 4-way split	Fail (population arithmetic)	Strong on population necessity	No per-district minority rationale; "8% on every demographic measure" not filed
2	Cochrane commuter tie	Partial support	Strong on within-Cochrane share; Strong on Calgary-as-largest-out-of-town	R1 claims fluid movement, not primacy; Calgary-Centre-vs-Foothills sub-claim not testable in CSD data
3	RMH–Banff NP extension	Not tested on stated grounds	Strong on s.15(2) area non-necessity (not a claim the minority made); ~491 area-weighted residents (not zero) per polygon-clipped DA pull; "no working ranches" statutorily entailed for in-park slice via *Canada National Parks Act*, unverified for adjacent Crown-land grazing-lease territory	"Ranching community of interest" was the audit's gloss; its verdict is withdrawn. Earlier "zero residents / zero ranches" framing has been corrected — see methodology file `banff_extension_population_check.md`
4	ODH reaching N Airdrie	Fail	Strong on population non-necessity	An earlier draft used the phrase "Census-of-agriculture data says" — that phrase has been removed from the current `report_public.md`; no Census of Agriculture extraction is filed. Suburban-vs-service-centre characterisation is descriptively true but not separately documented.
6	Red Deer–Sylvan Lake school and work ties	Partly supported	Strong on the commuting tie; Red Deer Catholic Regional serves both places	"8% of Red Deer's school-aged population" magnitude not filed
7	St. Albert–Sturgeon	Withdrawn	The maps do not converge (majority 2 districts, minority 3; C12)	No per-district minority rationale to test

Reading the table. *Recounted, two of the six claims fail on population arithmetic (Claims 1 and 4), two are partly supported (Claims 2 and 6), one was not tested on its stated grounds (Claim 3) and one is withdrawn (Claim 7). The earlier "five of six fail" counted a phrase the minority never wrote (Claim 3), a primacy claim it never made (Claim 2), a shared-division claim it never made (Claim 6), and a convergence that the official boundaries do not show (Claim 7).*

Disposition for the public summary. "Five of six fail" is not supported and should not be used; "two of six fail on population arithmetic, two are partly supported" is what the filed

evidence supports. The previous "six of seven" framing was retired earlier because (a) the seventh claim (Lethbridge) was a fabrication-by-paraphrase no underlying minority text supports and (b) the St. Albert-Sturgeon "no other configuration" claim was a counterfactual non-existence claim stronger than the filed evidence. The convergence framing that replaced (b) is now withdrawn as well.

Disposition for the remaining sub-claim corrections (Claims 1 and 6; Claim 4 resolved). The public-facing precision in Claims 1 and 6 ("within 8% of each other on every demographic measure"; "8% of Red Deer's school-aged population") is a stronger statement than the corresponding evidence file documents. **The honest options are:** (a) file the supporting calculation as a per-claim methodology note before publication; (b) soften the public-facing language to match the actual filed evidence ("the population arithmetic does not require it"; "Sylvan Lake and Red Deer have different public school divisions; one Catholic division serves both"). Option (a) preserves the quantitative precision; option (b) preserves evidentiary discipline at the cost of some rhetorical force. Claim 3 was not tested on its stated grounds (above), and the public report does not carry it. Claim 4's overstated "Census-of-agriculture data says" phrase has been removed from `report_public.md` (confirmed 2026-06-13); the current public report does not assert a Census of Agriculture comparison for Olds/Didsbury.

Bottom line for evidence-trail integrity. The rationale check separates the six claims; it does not condemn them all. The St. Albert-Sturgeon convergence framing is withdrawn. The remaining two sub-claim follow-ups (per-quadrant Airdrie demographic comparison; Red Deer-Sylvan Lake school-age magnitude) are evidentiary precision upgrades, not load-bearing. The Olds-Didsbury Census-of-Agriculture concern has been resolved by removing the overstatement from the public report (confirmed 2026-06-13).

5.9.7 Population data currency and the 2026 census

The Lunty committee's advisory panel drew a 91-seat map, delivered to the committee on October 22, 2026; the report had to go to the Assembly by November 2. The timing has an unaddressed population-data consequence.

Statistics Canada conducts a mandatory long-form census every five years under the *Statistics Act* (R.S.C. 1985, c. S-19). The 2021 Census of Population was collected May 11, 2021; population counts down to dissemination areas were released February 9, 2022. On the same cadence, the **2026 Census** was collected in May 2026, and its population counts are expected in early 2027.

The *Electoral Boundaries Commission Act*'s base is the 2021 census: s. 12(2)–(3) require the Commission to use the most recent decennial census, s. 12(4) substitutes a more recent province-wide census from which the population of every proposed division is available, and s. 12(5) allows more recent population information alongside either, which the commission used (a July 2024 estimate; C42). Section 12 binds the Commission, not an

Assembly committee. The 2026 census is not a decennial census under the Act, and its counts arrive in 2027, after the November 2026 deadline.

This matters most for the ridings where the audit's structural findings concentrate. The Calgary–Airdrie corridor — Airdrie (population 85,805 at the July 2024 municipal census; City of Airdrie, 2024), Cochrane, Chestermere, and Calgary's northwest quadrant — includes cities that grew 15–27 % between the 2021 census and their 2024 municipal censuses (Airdrie 15.8 % on the City's 85,805 above, as in `data/reference/alberta_population_plan_b.csv`, or 15.4 % on the 85,505 in the Municipal Affairs list; Cochrane 14.9 % and Chestermere 26.9 % on the Municipal Affairs list, `evidence/web/ma_population_list_2024.xlsx`; 2021 counts from `data/reference/alberta_2021_csd_populations.csv`). Alberta added approximately 200,000 residents in the 2021–2023 period alone (Alberta Treasury Board and Finance, 2023 population estimate). Boundaries drawn in 2026 on 2021 census populations, updated to 2024 estimates, for seats contested in 2027 and held on those boundaries through potentially 2031 will be built on population data 10 years old by the time the electoral cycle they govern ends. Population equality in the highest-growth ridings — the same ridings where the commission's two proposals diverge most sharply — will degrade fastest.

Policy implication. If the government's objective is redistricting serving effective representation through a full electoral cycle, a November 2026 completion date imposes a foreseeable cost: the map will begin with the most accurate population baseline available but will not be anchored to the 2026 census, whose counts arrive after it is drawn. No redistricting body can escape census timing constraints; the commission faced the same constraint. The observation here is forward-looking only: the committee and the legislature are aware 2026 census data will become available approximately one year after the committee's mandate ends, and the communities most affected by the audit's structural findings are precisely those where population drift from the 2021 baseline will be largest. This is not a legal objection to the November 2026 map; it is a relevant fact for any assessment of the map's durability.

5.10 Forward-looking AI-use recommendations for the Lunty committee

Audience and scope. The Select Special Committee on Electoral Boundaries, chaired by Brandon Lunty (MLA, Leduc-Beaumont), oversaw the review whose independent advisory panel drew a 91-seat Alberta map, delivered on October 22, 2026; the report had to go to the Assembly by November 2. This subsection was written before that map existed. It is a technical, non-partisan framework for how the committee — or its advisory panel, or any future Alberta redistricting body — can use AI tools responsibly if it chooses to. It does not take a position on whether the committee *should* use AI tools. It does take a position on

what disciplines any such use must follow. The position is not novel; it is the same methodological discipline this audit applies to itself (reproducibility, transparency, pre-registration, named accountability).

Why this section exists in this paper. The April 21 "AI academy" remark (Premier Smith, Alberta Hansard, April 21, 2026, p. 1564; reported in Calgary Journal 2026-04-21) signalled AI use is on the table for the committee. An audit documenting procedural departures from Canadian independent-commission practice (§5.9.2) without addressing the AI-use dimension would be incomplete — AI use can compound or mitigate the independence concerns already raised. A boundary map has legal and constitutional effect for up to a decade; the workflow producing it is part of its defensibility.

Seven core principles. Each is a discipline the committee's workflow must enforce, regardless of which tool is used:

1. **Humans decide; AI assists.** Every boundary in the final map must have at least one named committee member or advisor of record who will answer for it in public. "*The algorithm converged*" is not a defence.
2. **Transparency over opacity.** Every prompt, input dataset, model version, random seed, and output used in drafting must be logged, timestamped, and publicly released with the final report. Redact for personal privacy only, not for reputation.
3. **Reproducibility over one-shot generation.** Any AI output used in the map must be reproducible by an independent third party given the same inputs. Stochastic methods (MCMC, simulated annealing, LLM completions) require published seeds and pinned model versions.
4. **Pre-registration over post-hoc justification.** Evaluation criteria (population equality targets, COI priorities, compactness thresholds) must be published before any map draft is circulated, and treated as gates the map must clear — not as framing added after the draft.
5. **Independence tests over single-model reliance.** Any AI output on a load-bearing decision must be generated by at least two independent tools. Disagreements between tools are signals for human adjudication, not noise to average away.
6. **Falsifiability over rhetoric.** Every claim attached to the final map ("this preserves community of interest," "this reflects commuter ties") must be stated in a form naming the dataset which would confirm or refute it. Claims cannot be falsified must be labelled as opinion.
7. **Auditability over ease of use.** The cheapest workflow (an MLA types a question into a chatbot) is also the least auditable and therefore inadequate for a constitutional decision. The workflow making every step reproducible, even when slower, is the one the committee must adopt.

Specific technical recommendations (abbreviated; full text in the companion document).

- **Generation.** Use purpose-built redistricting software (GerryChain, Dave's Redistricting App, Maptitude for Redistricting), not a general-purpose chatbot. Publish the ensemble, not only the chosen map — a single map says nothing about whether the committee's choice is typical or an outlier within the constraint set. Do not use an LLM to write boundary descriptions directly; LLMs hallucinate street names and invert cardinal directions.
- **Evaluation.** Apply the same partisan-fairness metrics used in the academic literature (efficiency gap, mean-median difference, declination, seats-votes curve) against vote data from the three most recent provincial elections, not one. Run a Chen-Rodden natural-packing test: if the proposed map falls outside the 95th percentile of a constraint-bound ensemble in either direction, it requires a stated, testable explanation. Compute and publish Polsby-Popper and Reock compactness on every district.
- **Public input.** Publish the input corpus (redacted for personal information) so independent researchers can reproduce any AI-assisted theme coding. Do not rank submissions by length or signature count — electoral boundary decisions weigh arguments, not volume. Flag the *absence* of input as well as its presence.
- **Justification drafting.** Every factual claim in AI-drafted prose must be human-verified against a cited source. Do not let an AI generate the committee's interpretation of *Saskatchewan Reference* [1991] or s.15(2) — Canadian constitutional-law summaries from general-purpose LLMs are unreliable and occasionally invert the holding. Publish the prompts used for any passage appearing in the final report.
- **Data currency (census cycle lag).** Maintain the 2021 census as the statutory baseline for every s.15(2) test and every ±25 % determination (the Act requires it). *In parallel*, publish a "Plan B" sensitivity table using Alberta Treasury Board and Finance quarterly estimates. Report any ED whose legal-window status disagrees between Plan A and Plan B. AI's role in Plan B is limited to routine data-aggregation acceleration; every cell must trace back to a published TBF, StatsCan, or municipal-census figure. Full rationale at `findings/cycle_lag_analysis.md` + `docs/ai_use_recommendations_for_committee.md` §2.5.

What AI should not do — even with human review.

- Final decisions on district boundaries (a committee member signs each district, not a model).
- Weighing constitutional considerations (s.3 Charter analysis, *Saskatchewan Reference* application, s.15(2) criteria).
- Determining community of interest (lived experience is not retrievable from a census table).
- Drafting the committee's reasoning on contested districts (Airdrie, Chestermere, Nolan Hill–Cochrane, RMH–Banff Park, and any new 91-seat flashpoint).
- Assessing partisan intent (evidence cannot distinguish motive; AI cannot either).

Nine-item public-disclosure checklist. Before publishing the final map, the committee must be able to answer each of the following publicly: (1) which AI tools were used, by name and version; (2) what prompts and inputs were given to each; (3) which outputs were used in the final map and which were discarded; (4) what random seeds, configurations, and parameters were set; (5) which committee member or advisor takes personal responsibility for each district's boundary; (6) what evaluation criteria were established before drafting began; (7) what ensemble of alternative maps was generated and where the final map sits in the ensemble; (8) what Charter and statutory analyses were performed and by whom; (9) which claims in the final report are AI-drafted and human-verified, which are human-drafted, and which are AI-drafted without human verification. A committee able to answer all nine publicly has used AI responsibly. A committee unable to do so has not, regardless of tooling sophistication.

Three risks specific to the April 2026 context.

1. **Independence-washing.** The April 16 mandate includes an advisory panel of a chair plus two nominees from each side (two nominated by the Premier, two by the Leader of the Opposition). If the panel uses AI tools whose outputs are filtered through a UCP-majority MLA committee, the panel's independence is nominal. Remedy: publish the panel's AI outputs *in full* before the MLA committee acts on them, and require a written explanation for any substantive committee deviation from panel recommendations.
2. **Legitimacy-by-association.** An AI tool's output inherits only as much legitimacy as its inputs and operators provide. A map presented as "algorithmically generated" without disclosed prompts and constraint sets is borrowing technical legitimacy it has not earned. Remedy: the nine-item checklist above as a minimum disclosure standard.
3. **Acceleration past deliberation.** AI can generate thousands of candidate maps in hours and short-circuit the slow deliberative work a committee is supposed to do. Remedy: a proposed boundary is not adopted on the strength of a model run alone, even a well-designed one. Speed is not a virtue in redistricting.

Relationship to §5.9's procedural findings. The seven principles above do not replace §5.9's documented procedural departures from Canadian comparator practice; they supplement them. A committee adopting the AI-use disciplines and *also* operating under the April 16 MLA-committee-directed drafting structure retains the §5.9.2 procedural critique regardless of its AI workflow. AI discipline is necessary but not sufficient for a defensible process. The full AI-use document (with reference implementations and dataset pointers) is at docs/ai_use_recommendations_for_committee.md. Suggested citation: Conner, W., *AI-use recommendations for the Alberta Electoral Boundaries MLA Committee*, Alberta Electoral Boundaries Audit, v0.1, 2026-04-22.

---

6. Discussion

This section interprets the results of §5 against the prior work surveyed in §2 and forward-refers to §7 (Limitations and Falsifiability). The six-dimensional synthesis is presented first; the scope-discipline calibration and the three inherited qualifications follow.

DIMENSION	2019	MAJORITY 2026	MINORITY 2026	DIRECTION OF MINORITY SHIFT
§5.1.1 Population MAD from avg	2,886 (87 seats, 2017-report populations; a different base from 2026)	3,180	**4,707** (+48%)	wider dispersion
§5.1.2 Calgary Zone A – Zone B gap	(not run)	+0.36%	**+12.20%**	larger Zone A districts (packing signature not detected; C50)
§5.1.2 robustness (2023 winner-based)	(not run)	+0.39%	**+7.71%**	survives robustness check
§5.1.3 Rest-of-province mean population	(not run)	52,281	50,336 (−3.7%)	population-weighting shift below provincial average (*Carter*-permissible unless unjustified; flagged 2026-06-12 per T1.7 Referee #8 — Carter [1991] 2 SCR 158 *upheld* Saskatchewan's deliberate rural weighting, so "rural overrepresentation" was not an appropriate gerrymander-signature label)
§5.1.4 s.15(2) invocations statutorily legitimate	—	3 / 3	3 / 3	re-audit 2026-04-23 under corrected thresholds
§5.1.4 engineered-boundary signature	0	0	0 (RMH-Banff Park: E2 fails; Reading B withdrawn)	see §5.3.3
§5.2.1 Standard EG (Phase 4C)	−2.64% (*full statement of vote; +2.41% on the election-day votes the 2026 cells use*)	+0.04%	**+3.96%**	+3.92 pp more UCP-favourable (Phase 4C; S-M positive=UCP)
§5.2.2 blend sensitivity range (*superseded by Phase 4C*)	—	(*blend model retired*)	(*blend model retired*)	—

DIMENSION	2019	MAJORITY 2026	MINORITY 2026	DIRECTION OF MINORITY SHIFT
§5.2.1 Mean-median gap (NDP)	−2.22 pp (*full statement of vote*; −0.77 *pp on election-day votes*)	−3.64 pp	**+1.03 pp**	+4.67 pp shift more UCP-favourable (minority p99.97; majority p0.99)
§5.2.1 NDP seats at 50/50	47	**48**	43	minority −5 NDP seats vs majority at tied provincial vote
§5.8.2 Boundaries the commission majority flagged	—	0 (none flagged; the anomaly questions were built from the minority's boundaries)	4 flagged, 3 confirmed	three confirmed anomalies
§5.8.4 Airdrie splits	—	2 EDs	4 EDs by territory, 3 by people	one to two more pieces
§5.9 Procedural	—	Set aside by Government Motion 37	Set aside by Government Motion 37	same path for both maps; the process departs from comparators

Five correlated dimensions of evidence (not all independent — see §4.3.1) point in the same direction; the sixth, the procedural record, is the same for both maps and has no direction between them. Within the partisan-bias dimension, three of four pre-registered metrics (mean-median p99.97, declination p98.79, seats@50/50 p99.99) individually exceed the p95 pre-registered outlier threshold against the exploratory canonical ensemble (see §1 and §4.3.1 for the exploratory/confirmatory distinction); EG at p94.54 is directionally aligned but sub-threshold. The structural dimensions (population dispersion, Calgary zone gap, community splits, anomaly count) do not have equivalent point-estimate significance thresholds; the procedural dimension is qualitative. Together, the directional consistency across the five is the finding — the minority proposal, relative to the majority, shows more structural irregularities and, under 2023 voter geography, higher measured partisan-bias by three individually flagged metrics and one directionally aligned sub-threshold metric, across five measurement frameworks. (Note: the pre-correction formulation read "None individually crosses a statistical significance threshold"; the sign correction of Amendment 5, Part 9 changed declination from p1.21 NDP-tail to p98.79 UCP-tail, placing three of four above p95; corrected per T1.7 R2 Ref #5 2026-06-12.)

A 2019 enacted-map baseline (§5.4.10) adds structural context to this six-dimensional picture. The 2019 map was itself a mild joint-space outlier on the 1,010,000-plan canonical ensemble (Mahalanobis D^2=13.16, parametric p=0.0105). The majority 2026 proposal retreats toward the constraint-bound expectation (D^2=7.74, p=0.102), consistent with a normalizing commission process. The minority amplifies the 2019 anomaly 2.56-fold (D^2=33.64, p=8.80×10^{-7}) — measuring the void between what the two proposals do from a shared departure point.

Scope discipline and small-magnitude calibration. The six-dimensional framing is this paper's own: when single dimensions are underpowered, cross-dimensional agreement is the inferential artefact, not any individual magnitude. Each dimension's magnitude is small by design — the audit is not claiming a single five-alarm effect. Terms used in this paper carry calibrated meaning: *measurable* means "the computed statistic's sensitivity interval does not include zero at the stated confidence level"; *directional* means "the sign is consistent across all runs" without magnitude claim; *systematic* means "the same direction appears across multiple correlated dimensions (not all independent — see §4.3.1)." These are not

synonyms and are not interchangeable. A hostile reader entitled to read the audit as "the paper called small differences patterns" receives the following response: the patterns are defined precisely, apply to six correlated tests, and persist across three independent vote-attribution methods (centroid, area-weighted, and population-weighted MAUP, agreeing to within 0.1 pp; §5.2.7), across the uniform-swing probe on 338Canada's April 2026 polling (the crosswalk probe reverses by one seat), and across a symmetric test-selection audit revealing additional minority-map patterns (Lethbridge and Red Deer 4-way splits, §5.6) not present in the majority.

Multiple-comparison posture. A hostile reviewer may legitimately observe this audit runs on the order of 20 distinct statistical tests against overlapping 2023 vote data (four partisan-bias metrics × two maps × three attribution methods ≈ 24 tests, plus the non-partisan-bias dimensions), and ask whether a family-wise-error-rate (FWER) correction has been applied. The paper **explicitly does not apply a Bonferroni or Benjamini-Hochberg correction**, because the correction assumes the tests are independent significance claims — and this audit does not advance individual significance claims *as formal pre-registered hypothesis tests at* $\alpha = 0.05$. (Reporting that individual metrics exceed a pre-specified ensemble percentile threshold is a descriptive screening claim, not a classical hypothesis test; the distinction is explained in §4.3.1.) Every per-metric per-map result is checked against the 1,010,000-plan canonical ensemble's own percentile distribution (§5.4) and against three independent attribution methods agreeing to within 0.1 pp (§5.2.7), and the aggregate synthesis is framed as directional consistency across correlated dimensions, not as a count of independent rejections.

Applying Bonferroni to a consistency frame inflates false-negative rates on related measurements without correcting the actual inferential artefact (cross-dimensional agreement); the audit therefore uses a consistency-across-correlated-tests framing in preference to a multiple-comparison correction. Readers who prefer an FWER-adjusted lens should note (a) post-correction (Amendment 5, Part 9): three of four individual partisan-bias metrics (MM p99.97, declination p98.79, seats@50/50 p99.99) exceed the uncorrected p95 threshold; under 4-comparison Bonferroni (threshold p98.75), MM and s50 clearly survive and declination sits at the boundary; (b) the audit's positive claim does not depend on individual-metric significance — the directional consistency across five dimensions and the Mahalanobis joint-outlier score ($p=8.80\times10^{-7}$) remain the core framing regardless of correction strategy. (Pre-correction formulation said "the individual partisan-bias metrics do not cross their own uncorrected 95th-percentile sensitivity interval"; this was corrected 2026-06-12 (Amendment 5, Part 9).)

Three qualifications inherited from the stress-test pass narrow this synthesis:

- Under the Chen-Rodden (2013) natural-packing framing (see §5.2.5), Alberta's urban-NDP / rural-UCP geography sets each map's absolute partisan-bias level, but not the gap between two maps drawn on the same geography against the same ensemble, which §5.2.5 attributes wholly to drawing. The gap measures what the drawing choices do, not why they were made, so the claim is "the minority produces more UCP-favourable

results under 2023 voter geography," not "the minority was engineered against the NDP." The structural findings (§5.1 population equality, §5.1.2 Calgary zone gap, §5.8.2 visible anomalies, §5.8.4 community splits, §5.9 procedural) are not affected by the natural-packing caveat because they measure geographic and procedural properties the natural-packing argument does not address.

- Under RT3 (cross-election stability), the vote-based asymmetry keeps its sign when 2019 votes replace 2023 votes but shrinks from 3.92 pp to 0.83 pp, and the minority's EG falls inside the normal range. The structural dimensions do not depend on the electorate; the vote-based dimension (§5.2) is qualified accordingly.
- Under the submission-archive verification (§5.9.4), the procedural concern rests primarily on the two configurations without documented public support (Airdrie 4-way, Nolan Hill-Cochrane) rather than on the commission majority's full five-place statement, which held in three places and was partly wrong in two.

Direction disagreement: three-layer reconciliation. A careful reader of §5.2 and §5.4 will notice the partisan-bias metrics do not all point the same way, and the direction can flip depending on which vote input is used. This paragraph names each layer explicitly so they are not mistaken for methodological inconsistency.

Layer 1 — metric agreement under 2023 votes (sign correction of Amendment 5, Part 9 applied). B2 (efficiency gap), B3 (mean-median), B4 (seats at 50/50), and B6 (declination) all show the minority 2026 map as more UCP-favourable than the majority under Phase 4C and 2023 vote input: the minority produces substantially more NDP vote waste (EG +3.96% vs +0.04%), a more NDP-packed mean-median distribution (+1.03 pp vs −3.64 pp, placing minority at p99.97 in the UCP-tail), gives NDP five fewer seats at a tied provincial election (43 vs 48), and shows a corrected Warrington declination of +0.077 (p98.79 UCP-tail). Earlier drafts of this paragraph said "B6 declination disagrees" / "minority at p2.17 NDP-tail" — that was an artefact of a swapped-operand bug at `mcmc_ensemble.py:215` corrected 2026-06-12 (Amendment 5, Part 9 in `findings/pre_registration_amendment_log.md`). All four metrics now agree on the UCP-favoured direction; the asymmetric-packing reading at §6.2.2 is restated accordingly.

Layer 2 — vote-input dependence. At a tied vote on 2023 votes the minority gives the UCP 46 seats and the majority 41 (NDP 43 vs 48): a five-seat gap, not one (C27, C30). 338Canada's April 2026 per-riding projection (§Track J), run through the audit's hybrid crosswalks, gives the minority one more NDP seat than the majority (minority 23 NDP, majority 22 NDP). The canonical uniform-swing probe shows no reversal at any polling level (C7), so that one-seat flip is read as a crosswalk artefact.

Layer 3 — magnitude threshold (declination sign correction of Amendment 5, Part 9 applied). Under 2023 vote input and the 1,010,000-plan canonical ensemble (§5.4.9), three individual partisan-bias metrics carry outlier flags on the minority map: mean-median at p99.97 (UCP-favoured tail), **declination at p98.79 (UCP-favoured tail)**, and seats@50/50 at p99.99 (individual flag reinstated; n_eff=1,413). Efficiency gap at p94.54 remains below the p95

threshold and is not flagged (directionally aligned with the other three, but not a tail flag; p94–p97 under the constrained runs). The majority is not flagged in the UCP-advantage direction on any metric (EG p16.52, declination p21.85, seats@50/50 p78.54); it sits at p0.99 on mean-median on the NDP-cracking tail (pre-registered Row 8, expected direction). The aggregate finding rests on the joint Mahalanobis result ($p=8.80\times10^{-7}$) and on directional consistency across the structural dimensions (§5.1, §5.8, §5.9).

Summary of the direction picture. Under structural tests, the direction is unambiguous and multi-confirmed. Under partisan-bias tests, all four standard metrics (EG, mean-median, seats@50/50, declination) agree that the minority is more UCP-favourable under 2023 votes (declination sign-convention corrected 2026-06-12, recorded in Amendment 5, Part 9; see Layer 1 above). The sole directional reversal is on the crosswalk-based seat count at April 2026 polling levels (§Track J: 338Canada April 2026 projection gives the minority one more NDP seat than the majority). A reviewer citing 338's April 2026 numbers as evidence the minority is the *fairer* map is making a legitimate point about one layer of the evidence; the audit does not suppress the layer and reports it in §Track J. The audit's overall position is that the ensemble result carries the partisan evidence; the structural dimensions compare the two maps with each other, and on those dimensions the direction is stable.

6.1 How to interpret these findings — NP-hardness, statistical improbability, and precision as armor

The results above are NOT findings of "the correct map was X and the Commission drew something different." The redistricting problem is **NP-hard**: the Alberta *Electoral Boundaries Commission Act* constraints (the ±25 % population band; the s.14 considerations, among them community of interest, geography and municipal boundaries; the s.15(2) exception for up to four sparse divisions meeting three of five criteria, one of which is a reserve or Métis settlement; and public-hearing input) do not admit a unique optimum. No mathematical procedure produces *the* correct Alberta map; any map satisfying the constraints is one of an enormous family of legal maps, and the space of legal maps contains trade-offs — preserve COI at Airdrie at the cost of a slightly wider population dispersion, or tighten population equality at the cost of splitting Airdrie. These are not errors; they are **choices**. Fairness in this domain is not a discovery; it is a negotiation.

The audit therefore does not say **"this map is wrong."** It says "**this map is statistically improbable within the constraint set, and the improbability has a measurable direction.**" Three concrete translations of the main results into the language:

- **Airdrie fragmentation (§5.3.2).** Airdrie's population of approximately 85,805 at 2024 vintage sits at 1.56× provincial quota [City of Airdrie, 2024]; the statutory ±25 % band requires *at least* a 2-way split and permits a clean 2-way split (corrected 2026-06-12 per T1.7 R2 Ref #11 — earlier drafts erroneously said "a single-ED draw or a clean 2-way split"; single-ED is mathematically infeasible at the 2024 vintage). The share of neutral ensemble plans that keep Airdrie in two districts has not been tabulated. **The minority commissioners could have kept Airdrie in two districts. They chose four (three by**

people), among many legal alternatives. The audit's question is not "why isn't Airdrie whole?" It is: "given the constraint set permitted a clean 2-way, why was a 4-way split selected?"

- **Population dispersion (§5.1).** The mean absolute deviation of ED population from the provincial quota is 3,180 on the majority and 4,707 on the minority — a 48 % wider dispersion. The constraint set permits both: the ±25 % population deviation band leaves room for either. **The minority commissioners did not have to draw a map with 48 % wider dispersion; they chose to, among many constraint-legal alternatives** (on the commission's 2024 tables; on the 2021 census the maps are almost level, Appendix C). (*The municipal-anchoring example previously listed in this position did not survive canonical recomputation — both maps are close to the 2019 map's 75.1 %. See* §5.8.5.[3])
- **MCMC constraint-bound expectation (§5.4).** The ReCom ensemble places the minority map at the p99.97 tail on mean-median (canonical 1,010,000-plan run; §5.4.9). Interpretation: the ensemble samples 1,010,000 plans; the minority map sits further into the UCP tail on mean-median than 99.97 % of them. **The minority commissioners were not forced to draw a p99.97-tail map. They produced one, among hundreds of thousands of legal alternatives closer to the constraint-bound expectation.**

In every case, the audit's claim is the same shape: the minority's map carries a measurable **fairness cost** relative to what the constraints allowed, where "fairness cost" means the number of statistical standard deviations (or the ReCom-ensemble percentile, or the anchoring ratio) by which the chosen map is displaced from the constraint-bound expectation. **This is the audit's only substantive claim.** It does not claim the minority is "wrong"; it claims the minority is improbable by a measurable amount, and the improbability has a direction.

6.2 Author's verdict — was either map a gerrymander?

This subsection departs from the audit's measurement-only voice and offers the author's stated opinion on the question motivating this work. It is presented as opinion, not as a peer-reviewed conclusion. The author's prior — UCP-disinclined Alberta voter — is disclosed in the Author disclosure block, along with the three findings retained in this paper running *against* the prior. Readers who weight the audit only on its measurable claims should stop at §6.1 and treat this subsection as ignorable.

A note on what "verdict" means here. The audit cannot judge intent; intent is not observable from public data, and the Author disclosure block already commits the paper to this restraint. What the audit *can* do is observe and quantify *effects*, and report the pattern those effects form. If the pattern looks like a gerrymander signature in the academic literature, the audit says so. Whether the signature reflects deliberate engineering or unlucky choice among legal alternatives is a question for the reader to weigh; the audit's job is to make sure the evidence on which the weighing happens is on the table.

Definition of the pattern this section evaluates. A "gerrymander signature" is the constellation of measurable effects the academic redistricting literature (Stephanopoulos and McGhee 2015; DeFord et al. 2021; Warrington 2018; Katz, King and Rosenblatt 2020) treats as evidence of partisan engineering. Narrower than "any map with a partisan-asymmetry signal" (which would over-fire on natural-packing geography); broader than "any map whose author admits intent in writing" (essentially never observable). It maps onto the Canadian *Saskatchewan Reference* [1991] framework as: a map fails effective representation when its measured effects systematically dilute one community of voters' electoral weight in a way that **cannot be justified by any of the *Carter* factors** (geography, community history, community interests, minority representation, or better government). Earlier drafts used the formulation "beyond what geographic constraints require" — that is a *necessity* test *Carter* rejected. The corrected definition (per T1.7 Referee #8) tracks *Carter*'s actual holding: deviations need only be *justified* by a Carter factor, not strictly *required* by geographic constraints. The audit measures the effects; the constitutional question of whether those effects amount to a failure of effective representation is for counsel and a court to assess (Appendix F).

6.2.1 Lane 1 — Partisan-bias magnitude (against Alberta-calibrated thresholds)

The audit's §5.2.8 derives **four Alberta-calibrated EG thresholds**, of which the most empirically grounded is the MCMC-ensemble 95th percentile drawn from 1,010,000 ReCom plans of 87 contiguous districts, balanced to ±12.5% at the proposal step within the Act's ±25% band (community of interest not modelled). None of these thresholds is borrowed from US federal judicial standards; each is calibrated to Alberta law or Alberta data. The full provenance of each threshold is in §5.2.8; the cross-tabulation against both 2026 maps follows.

The Lane 1 verdict uses **Phase 4C spatial attribution** as the sole canonical measurement (`packing_cracking_analysis.py` v0.3, 2026-05-18; exact VA-level centroid-in-polygon on official EA shapefiles). The two earlier attribution layers are retired: Reading A (crosswalk-blend, Layer 1) is superseded by Phase 4C (§5.2.2); Reading B (spatial against v0_8 DPG geometry, Layer 4) used geometries derived from commission PDF thumbnails — the DPG sunset clause is satisfied by Phase 4C on official shapefiles (§4.1.4). Phase 4C EG: majority +0.04%, minority +3.96% (S-M positive=UCP-favoured), consistent with canonical MCMC (majority +0.10%, minority +4.02%) to within 0.06 pp.

THRESHOLD	SOURCE	VALUE	PHASE 4C MAJORITY +0.04%	PHASE 4C MINORITY +3.96%
Stephanopoulos & McGhee (2015) reference	US historical calibration	7%	sub-threshold	sub-threshold
Option A — Assembly-size sensitivity	First-principles scaling: 2/89 seats	~2.2%	sub-threshold	**over threshold**

THRESHOLD	SOURCE	VALUE	PHASE 4C MAJORITY +0.04%	PHASE 4C MINORITY +3.96%
Option B — EBCA statutory-proportional	One-fifth of EBCA ±25%	5%	sub-threshold	sub-threshold
Option C — Alberta historical-swing	2015/2019/2023 swing analysis	1.01–9.71%	sub-threshold in all contexts	sub-threshold under 2023 (p94.54) and 2019 (p70.4) contexts; **over under 2015** (+10.54%, p99.45)
Option D — MCMC ensemble p95	**1,010,000-plan canonical (official EA shapefiles, seed 1432864451, ±25% accept band, ±12.5% proposal step)**	**4.10%**	sub-threshold (p16.52)	sub-threshold (p94.54; 0.14 pp below 4.10% threshold)

Lane 1 verdict. *Under Phase 4C canonical attribution, the majority is sub-threshold on all Alberta-calibrated options — a clean Lane 1 result (p16.52 on canonical ensemble). The minority exceeds the assembly-size Option A threshold (2.2%) and, under 2015 electoral-context votes, exceeds the Alberta historical-swing Option C ceiling (9.71%). Under 2023 votes — the operative electoral context for the 2026 boundaries — the minority falls just below the Option D canonical ensemble threshold (p94.54; 0.14 pp below the 4.10% threshold). The qualitative framing the §6.2 verdict ultimately rests on — the* ***structural differences*** *distinguishing the two maps live in the structural lane (§6.2.2), not the partisan-bias-magnitude lane — is robust to Phase 4C. The majority is clean on EG magnitude; the minority is near but below the most stringent Alberta-calibrated threshold under current electoral conditions.*

Effect Size Interpretation (updated 2026-07-12 for cleaned 1,010,000-plan canonical rerun; prior updates 2026-05-10 for 1,010,000-plan canonical run; joint-statistic framing revised 2026-06-10; declination sign corrected 2026-06-12, recorded in Amendment 5, Part 9). Under the 1,010,000-plan canonical ensemble (official EA shapefiles, seed 1432864451, §5.4.9), the minority map places at p99.99 on seats@50/50 — 69 of 1,010,000 neutral plans exceed its canonical value of 51.69%, all at 45/87. The parametric Ch1 value (Mahalanobis, $p = 8.80\times10^{-7}$; 89-district maps against 87-district plans, size-matched test pending), doubled for the two channels examined, is $p \le 1.76\times10^{-6}$ (≈ 1 in 568,000); it is a model extrapolation, and the sample alone supports p below about 6.9×10^{-4} — **exploratory, not pre-registered; see §1.2**; see §4.3.2 for why this bound replaces the earlier Fisher combination (~4.61×10^{-8}, retired for assuming channel independence Ch1/Ch2 do not have — not an artefact of the since-corrected chain-1 duplication) (SZAT is retained as exploratory only — its standard-permutation result does not survive block-permutation null correction). The earlier DPG-era estimate (p=0.015, +2.21 pp vs neutral median, Cohen's d=0.31) is superseded. On the 1,010,000-plan canonical ensemble, **three partisan metrics carry tail flags (≥p95) simultaneously: MM at p99.97 (UCP-tail), declination at p98.79 (UCP-tail under the corrected Warrington convention; earlier drafts cited p1.21 NDP-tail under the swapped-operand δ_audit = −δ_Warrington convention now retired), seats@50/50 at p99.99**. EG at p94.54 falls *just below* p95 and **is not counted as an outlier flag** under the audit's pre-registered 4.10% / p95 Alberta-calibrated threshold — though EG is directionally aligned with the other three. The minority crosses three of four pre-registered partisan flags; the joint-tail bound above incorporates the three-flag tail pattern plus EG's directional alignment, not a four-tail reading. The three-tail-flag pattern is consistent with asymmetric packing: the minority

over-concentrates NDP votes in high-share districts (MM and seats flags) while also producing unusually tight winning margins for NDP-won districts that translate into UCP-favoured declination geometry (declination flag). An unexpected finding from the 1,010,000-plan run: the majority map's mean-median places at p0.99 — also in the extreme NDP-tail (see §5.4.9 narrative). Both real maps are statistical outliers on at least one metric; the minority is the more extreme on three of four.

6.2.2 Lane 2 — Structural and procedural pattern

Lane 1 having returned a clean result for the majority on partisan-bias magnitude and a near-threshold result for the minority (p94.54; majority sub-threshold at p16.52), the question becomes whether the structural evidence reinforces the Lane 1 signal. The audit's other test families are vote-data-independent and describe differences that don't show up in EG magnitude alone.

TEST FAMILY	THRESHOLD (WHERE DEFINED)	MAJORITY 2026	MINORITY 2026
Mean-median percentile vs MCMC ensemble	p > 95 (UCP-tail) = outlier; p < 5 (NDP-tail) = opposite-direction outlier	**p0.99 (NDP-tail; opposite direction from UCP-gerrymander hypothesis; possibly a commission-convention effect, untested — §5.4.9; see §6.2.3)**	**p99.97 (UCP-tail outlier; p99.8 or higher on the constrained runs — §5.4.9)**
Municipal anchoring	compared with the 2019 map's 75.1 %	80.0 %	71.8 % — not a divergence signal on canonical geometry[3]
Population MAD	tighter is better	3,180	**4,707 (48 % wider on the 2024 tables; almost level on the 2021 census)**
Calgary geographic-zone gap	smaller is more neutral	0.4 %	**12.2 %**
Chair-flagged geographic anomalies (registered name; the commission majority's objections)	count, lower is better	0 (the majority flagged none on its own map; the minority report's criticism of the majority is not counted)	**3 of 4 flagged, confirmed** (RMH–Banff Park, Nolan Hill–Cochrane, Olds → N Airdrie)
Airdrie community split	2 is the minimum	2-way	**4 by territory, 3 by people**
Rationale-failure pattern (symmetric audit; **qualitative, not pre-registered**)	0 of contested redraws fails	not applicable	**2 of 6 fail** on population arithmetic; 2 partly supported; 1 not tested on its stated grounds; St. Albert-Sturgeon withdrawn (§5.9.6; an earlier seventh — Lethbridge federal-boundary match — was dropped from the draft as unsourced)

TEST FAMILY	THRESHOLD (WHERE DEFINED)	MAJORITY 2026	MINORITY 2026
Public-submission support for contested configurations	every contested config has documented support	n/a	**2 configs (Airdrie 4-way, Nolan Hill) have no documented supporting submissions** in the 1,345-submission archive (no submission could address the minority's maps)
Structural-irregularity count (tests written down April 24, 2026, and the 4-of-5 line April 25, after both maps were measured; dated in the repository, not on OSF)	4 of 5 = the audit's line	0 of 5	**4 of 5** — at the line[3]

Lane 2 reading. *The minority meets four of five structural tests, at the audit's line of four; the majority meets none. These tests compare the two commission maps: the registered November structural lane, whose thresholds are midpoints between them, fires on 93.5% of neutral 91-district maps and 95.5% of neutral 89-district maps, so a structural result shows resemblance to the minority map, not departure from neutral.* ***Note on anchoring:*** *the DPG-era 4.9× anchoring departure did not survive canonical recomputation (both maps are close to the 2019 map's 75.1 %, at 72% vs 80%)[3] and is not carried forward as a standalone signal. The evidential core is Lane 1's MCMC ensemble (parametric p = 8.80×10⁻⁷; 89-district maps against 87-district plans, size-matched test pending). Lane 2 adds four geometry-independent structural dimensions: population dispersion (48 % wider on the 2024 tables), Calgary zone asymmetry (12.2 % vs 0.4 %), Airdrie fragmentation (4 vs 2 districts by territory, 3 vs 2 by people), and spatial anomalies (3 of the 4 boundaries the commission majority flagged, confirmed). The rationale check, recounted, finds two of six contested configurations failing on population arithmetic, two partly supported, one not tested on its stated grounds and one withdrawn (§5.9.6); it no longer supports a "five of six" reading. (The audit had previously listed a seventh configuration — Lethbridge / Taber-Warner federal-boundary match — which was dropped from the draft because the underlying minority claim cannot be located in the report; see* `analysis/methodology/reference/lethbridge_federal_boundary_check.md`.)

6.2.3 Verdict on the majority 2026 proposal: not a gerrymander

Both lanes return a clean result. On partisan-bias magnitude (Lane 1), the majority crosses no UCP-tail Alberta-calibrated threshold. On structural dimensions (Lane 2), the majority crosses no UCP-tail threshold. The canonical 1,010,000-plan run (§5.4.9) finds the majority mean-median at p0.99 — an NDP-tail reading (opposite direction from the UCP-gerrymander hypothesis) — and §5.4.9 offers a possible, untested explanation, a commission-convention effect: the ReCom-typical neutral ensemble is free to dissolve rural districts a commission legally must preserve, pulling the neutral distribution's mean-median higher than commission constraints allow. Per the severity-audit disclosure at §5.4.9 (T1.17), that explanation would apply equally to the minority. The constrained runs (§5.4.1) keep the minority's three tail flags at p98.3 or above under both seeds: further out under the majority seed, slightly in under the minority seed. All other majority metrics are within null (EG p16.52, declination p21.85, seats@50/50 p78.54, population MedAD p15.9 under the ±12.5% proposal band); Mahalanobis p=0.125 (50k pre-reg) / p=0.102 (1,010,000-plan canonical). Under canonical 1,010,000-plan geometry, the majority also retreats from the 2019 enacted baseline in joint-metric space (D^2=13.16 → 7.74; see §5.4.10), consistent with a normalizing commission process. The Chen-Rodden decomposition (§5.2.5–§5.2.6)

attributes the majority's UCP-favourable point to dispersed rural margins rather than to drawing choices.

My verdict: the majority is the kind of map a competent independent commission would produce. It is not a gerrymander on any Alberta-calibrated metric.

6.2.4 Verdict on the minority 2026 proposal: exhibits a gerrymander signature on the structural lane; coverage-sensitive on the partisan-bias-magnitude lane

The honest reading of the two lanes:

1. **On partisan-bias magnitude (Lane 1) — Phase 4C canonical verdict (official EA shapefiles, 1,010,000-plan ensemble; authoritative per §6.2.1, supersedes Reading A and Reading B).** Three of four pre-registered partisan-bias metrics individually flag the minority map in the UCP-favoured tail: mean-median p99.97, declination p98.79 (sign correction of Amendment 5, Part 9 applied), seats@50/50 p99.99. **Note on the constrained runs (T1.17; C24):** a constraint-enforcing ensemble has been run. It keeps the three tail flags at p98.3 or above under both seeds — further out under the majority seed, slightly in under the minority seed — so the percentiles are not shown to be conservative lower bounds. Efficiency gap at p94.54 is directionally aligned but sub-threshold (pre-registered Alberta-calibrated floor: p95 / 4.10%). The joint Mahalanobis D^2=33.64 places the minority at p=8.80×10^{-7}. Under the retired DPG-era attribution layers: under crosswalk-blend (Reading A, retired per §6.2.1) the minority was sub-threshold on every Alberta-calibrated threshold; under v0_8 full-coverage spatial (Reading B, retired per §6.2.1, Run #4 in §5.4.4) the minority was over every threshold including the MCMC-derived 4.10 % at p100. Both readings — and Phase 4C canonical — agree the minority sits in the UCP-favoured tail; they differ on whether individual metrics cross their thresholds. Phase 4C canonical is the authoritative reading (3-of-4 individual flags + joint p=8.80×10^{-7}).
2. **On structural and procedural patterns (Lane 2) the minority meets four of five structural tests, at the audit's line (anchoring does not fire).**[3] These tests compare the two commission maps; the registered November structural lane fires on most neutral maps (93.5% of 91-district, 95.5% of 89-district), so they show difference from the majority map, not departure from neutral. Of six contested redraws, two fail their stated rationales on population arithmetic, two are partly supported, one was not tested on its stated grounds and one is withdrawn (§5.9.6; an earlier seventh — Lethbridge federal-boundary match — was dropped from the draft as unsourced). The commission majority flagged four boundaries on this map, three confirmed by the audit, and none on the majority map; the minority report's criticism of the majority is not counted this way. Lane 2 is invariant across the coverage-attribution choice. Under canonical 1,010,000-plan geometry, the minority amplifies the 2019 enacted baseline's joint-space position (D^2=13.16 → 33.64), adding context to the Lane 2 reading without introducing an independent test (see §5.4.10).

Under Phase 4C canonical, the two lanes both point in the same direction. Lane 1 has three of four metrics individually above p95 and joint Mahalanobis p=8.80×10^{-7}; Lane 2 meets four of five structural tests. A reader who limits Lane 1 to individual EG and counts only the sub-threshold p94.54 result may read the minority as not exhibiting a gerrymander signature on the EG dimension — but the three individually-flagged metrics, the joint D^2 result, and Lane 2 together point toward one. Katz, King and Rosenblatt (2020) argue no single magnitude metric is dispositive and that any valid measure must satisfy symmetry; the audit's ensemble measures departure from neutral plans, not from symmetry, and in absolute terms the minority is closer to an even split at 50/50 than the majority. The flag, rationale and submission patterns are not partisan-bias measurements; they describe how the minority's choices were received and justified, and say nothing about intent.

The verdict the audit's measurements support. On the cumulative structural-and-procedural pattern, the minority 2026 proposal exhibits the constellation of effects the academic literature treats as a gerrymander signature. On the partisan-bias-magnitude lane under Phase 4C canonical, three of four individual metrics are above their pre-registered thresholds, and the exploratory joint score is p = 8.80×10^{-7} (89-district maps against 87-district plans; size-matched test pending); EG alone is directionally aligned but sub-threshold. (The DPG-era verdict before the sign correction of Amendment 5, Part 9 used Reading A/B framing — Reading A sub-threshold on every metric, Reading B over every metric; both readings are retired per §6.2.1 in favour of Phase 4C canonical.) Whether the observed effects reflect deliberate engineering against the NDP, unlucky choice among legal alternatives, or some combination of the two is a question the audit cannot answer from public data alone. The author's restraint on intent is a deliberate methodological choice, not an evasion: intent is not observable from boundary geometry, vote totals, public submissions, or chair-flag counts. What is observable is the pattern of effects, and the pattern is reported above without hedging.

A reasonable expert who weights partisan-bias magnitude over structural pattern would reach a more cautious verdict on the minority — closer to "no measurable gerrymander signature on the partisan-bias dimension; structural irregularities require explanation but do not by themselves establish anything about how the map was drawn." This disagreement is documented rather than hidden.

6.2.5 How close did the minority come?

A "how close" answer needs to be lane-specific because the two lanes give different answers.

Lane 1 (partisan-bias magnitude) — Phase 4C canonical (authoritative; supersedes Reading B below). Under canonical 1,010,000-plan ReCom on official EA shapefiles: mean-median p99.97 (UCP-tail), declination p98.79 (UCP-tail; sign correction of Amendment 5, Part 9 applied), seats@50/50 p99.99 (69 of 1,010,000 neutral plans exceed it, all at 45/87). Efficiency gap +3.96 % at p94.54 — directionally aligned but 0.14 pp below the pre-registered p95 / 4.10 % Alberta-calibrated threshold. The Cannon et al. (2023) short-bursts

test (§5.4.8) reaches 46 of 87 UCP seats at 50/50 (52.87 %) in 40,000 hill-climbing steps, against the minority's 46 of 89 (51.69 %); the two counts sit on different denominators, and on official geometry 69 neutral plans also exceed the minority (§5.4.8), so the hill-climb no longer separates the minority from neutral procedures. **Distance to Phase 4C thresholds: three individual metrics (MM, Decl, s50) above p95 and above the 4-comparison Bonferroni threshold for MM and s50; EG at p94.54 is 0.46 percentile points below p95 on the individual flag but directionally aligned.** DPG-era Lane 1: Under Reading B (retired, full-coverage spatial, Run #6 2M), the minority's EG was +9.21 % at p100 of the 2,000,000-map ensemble; on seats@50/50 (89-of-89 attribution, §5.4.7), 52.8 % sat above the 2M-ensemble converged ceiling of 51.72 %. These DPG-era figures are superseded by Phase 4C canonical and should not be cited independently.

Boundary-choice decomposition (SZAT, exploratory, §5.2.10). The SZAT bootstrap (p=0.0024 under standard i.i.d.-flip permutation, AsPredicted #289,469) is retained as exploratory context. Under a block-permutation null correcting for spatial autocorrelation across adjacent Voting Areas, SZAT returns p≈0.19 — not significant — and is therefore retired as a confirmatory channel. The regional decomposition of the SZAT score (+0.039211 total) is: Rest of Alberta +0.015 (dominant), Edmonton +0.008, Mountain-West / Canmore-RMH +0.006, Calgary −0.008 (partially offsetting). These terms sum to +0.021; the rest is not attributed by region. The signal is distributed across the province; Calgary swing zones run in the *opposite* direction to the headline score. This is inconsistent with a Calgary-centric explanation of the minority's UCP-favourable position. The parametric Ch1 value (Mahalanobis, $p=8.80\times10^{-7}$) doubled for the two channels examined is $p \le 1.76\times10^{-6}$ (~1 in 568,000) — a model extrapolation, exploratory, not pre-registered (§1.2); see §4.3.2.

Lane 2 (structural pattern). Against the audit's own lines:

- Mean-median percentile p99.97 vs literature outlier line p95 — **~5 percentile points over** (canonical 1,010,000-plan run; 50k preliminary run had p99.99)
- Structural-irregularity count 4 of 5 vs the audit's cut-off of 4 (written down after both maps were measured) — **at the line**[3]
- Boundaries the commission majority flagged: 4 (3 confirmed) vs 0 — a one-sided count; the minority report's criticisms of the majority are not scored this way
- Airdrie 4 districts by territory (3 by people) vs the 2-district minimum — **one over by people**
- Rationale check: 2 of 6 fail on population arithmetic, 2 partly supported, 1 not tested on its stated grounds, St. Albert-Sturgeon withdrawn (§5.9.6; an earlier seventh — Lethbridge federal-boundary match — was dropped from the draft as unsourced)
- SZAT 2019→minority score = +0.016 (p=0.053; the reported null CI [−0.017, +0.006] does not square with that p, so the result is borderline); minority boundary choices moved EG in the UCP-favoring direction relative to 2019 — consistent with but not establishing a pattern of directed movement (exploratory, not pre-registered; see §5.4.10)

Distance to the structural line: 0 (at the line of four). On the structural lane the minority meets four of five tests; anchoring does not fire.

The honest summary: *the minority meets four of five structural tests; on partisan bias it is over the 2.2 % EG line and, under 2015 votes, the historical-swing line; under 2023 votes it is just below 4.10 %, with three of four partisan metrics past p95.* This is the observed effect. How the map came to be drawn this way is not observable from public data.

6.2.6 What would change the author's verdict

1. **A demonstration that no constraint-legal Alberta map satisfies the minority's stated COI rationales (community-of-interest preservation in Airdrie, Cochrane, Nolan Hill, RMH–Banff Park) and *also* matches majority-comparable municipal anchoring (≥ 60 % CSD/DA edge alignment).** The minority's rationale-failure pattern would then be evidence of a constraint trade-off rather than engineering, and the finding would be weakened, or retracted if the evidence is decisive. The test is the counter-map challenge in Issue #14 on the audit's GitHub repository, judged by these criteria: a counter-map that meets them strengthens the finding, because it shows the minority's low anchoring was not required by its stated reasons. Strongest single falsifier. On the official boundaries the test is moot: both maps already clear its ≥ 60 % anchoring bar (minority 71.8 %, majority 80.0 %; §5.8.5, `data/outputs/municipal_anchoring_canonical.json`). (Corrected by Amendment 5, Part 22: an earlier version of this item read a successful counter-map as the falsifier, which reversed the inference.)
2. **The direction flips under more recent polling.** Currently the polling supports the 2023 direction; if more recent polling shows the direction flipping under multiple 2020s-era voter distributions, the structural pattern would become harder to read as engineering. (Amendment 5, Part 28 struck this item's former premise, a 2019 direction reversal: on the official 2019 files the minority stays the more UCP-favourable map, C44.)
3. **A pre-2026 internal commission document is published showing the minority's anchoring and split choices were a deliberate response to documented community submissions rather than drafting choices.** The §5.9.4 submission-archive verification could not find such submissions for two of the contested configurations; if they exist and were missed, the rationale-failure finding is wrong.
4. **A structural result on the panel's 91-seat map would not, by itself, change the verdict.** The registered November structural lane (replicated at 3 or more of 5 flags) fires on about 93.5% of neutral 91-district maps, so a minority-range score shows resemblance to the minority map, not departure from neutral; the partisan lane carries that test.

The audit's pre-registration commits the author to publishing any of these retractions publicly within 30 days of receiving the falsifying evidence.

6.2.7 Verdict on the April 16 government pivot itself

Separate question, addressed in §5.9.2 as a procedural finding. The author's opinion: replacing the commission's process with a UCP-MLA-chaired committee and its advisory panel during the same redistricting cycle is the most government-controlled response among the cases reviewed in §5.9.3. It is not, on its own, evidence the panel's map will be a gerrymander. In my view it weakens the procedural guardrails normally relied upon to make redistricting credible to the losing party, relative to comparator practice. The panel's map will be scored under the same scorecard applied to the two commission proposals. A structural score in the minority's range would not settle this opinion, because the structural lane fires on most neutral maps; the partisan lane is the informative test.

6.2.8 Bottom line

- **Majority 2026:** does not exhibit a gerrymander signature on either Alberta-calibrated lane.
- **Minority 2026 (Phase 4C canonical — authoritative):** three of four pre-registered partisan-bias metrics flag the minority individually in the UCP-favoured tail (mean-median p99.97, declination p98.79, seats@50/50 p99.99; 69 of 1,010,000 neutral plans exceed the minority's canonical s50 value, all at 45/87); efficiency gap +3.96 % at p94.54 is directionally aligned but sub-threshold (0.14 pp below the pre-registered p95 / 4.10 % Alberta-calibrated floor); joint Mahalanobis $p=8.80\times10^{-7}$; and meets four of five structural tests, which compare it with the majority map rather than with neutral maps. The Cannon et al. (2023) short-bursts hill-climb reaches 46 of 87 UCP seats at 50/50 (52.87 %; the minority has 46 of 89) (§5.4.8). The DPG-era Reading B figures (EG +9.21 % at p100 of 2M; s50 = 52.8 % above 2M ceiling) are superseded per §6.2.1. On partisan bias the minority sits in the extreme tail of neutral plans; on structure it differs from the majority map, not from neutral maps. The audit reports the effects; what those effects suggest about how the map was drawn is for the reader to weigh.

Neither summary is a legal finding. Both are an attempt to give the citizen-reader of this audit a plain answer to the question they probably came here with — calibrated to Alberta's own thresholds, not to US federal judicial standards. The audit's restraint on intent is deliberate: intent is not observable from public data, and the pattern of effects the audit *can* observe is reported plainly enough the reader does not need the author to draw the inference for them.

Why this level of methodological precision? The audit's apparatus — seven measurement layers, three-chain R-hat convergence, DPG tier-aware perturbation CIs, machine-readable dependency DAG, pre-committed pass criteria, per-finding retraction pathway — is deliberately over-engineered relative to the Commission's drawing process. The Commission drew with a broad brush (political negotiation, public-hearing notes, professional judgement). The audit looks through a microscope (adjacency chains, surplus-vote rates, constraint-bound percentiles). This asymmetry is intentional: **precision is armor**. If the audit presented a single number — "the minority's Efficiency Gap is 2.4σ from neutral" — the Commission would legitimately respond "Alberta's geography is unusual;

your one number is too simple to capture it." The over-engineering forces the distinction between an accidental brush-stroke and a systematic pattern, and it is what allows the audit to answer the Commission's legitimate objections in advance.

Translation discipline. The math provides authority; the prose provides conviction. The table in §6 above is the audit's formal synthesis. The three bulleted translations above are the audit's human-readable reading of the synthesis. Both are included because neither alone is sufficient: math without translation is unactionable for a reader who is not a redistricting specialist, and translation without math is polemic. This section exists to bridge them explicitly.

What the audit does not claim. It does not claim intent (§4.5 is explicit). It does not claim the Commission acted in bad faith. It does not claim any specific individual commissioner is responsible for the minority's patterns. It claims only the minority map, relative to the majority map drawn by the same Commission under the same statutory constraints on the same voter geography, is displaced from the constraint-bound expectation in a measurably consistent direction across four of five structural dimensions. The explanation for the displacement is not within the audit's scope; the measurement is.

---

7. Limitations and Falsifiability

7.0 Hypotheses tested during the audit and their disposition

The audit's central directional claim (*minority more UCP-favourable than majority across population, spatial, partisan-bias, and procedural dimensions*) is one of several working hypotheses running through the project. Three of those working hypotheses did not survive contact with the data and are recorded here as part of the audit's evidentiary discipline. The 2026-04-26 external code audit by Google Gemini 3.1 Pro (full memo at `analysis/review/external_audit_gemini.md`) and the falsification tests subsequently run against the audit's own pipeline produced this disposition. The seven-character commit hashes in the table predate the 2026-05-12 history rewrite (§5.4.9) and do not resolve in the current repository; a file no longer in the tree is in the git history before the eight-character commit named beside it.

#	HYPOTHESIS	FINAL DISPOSITION	WHAT KILLED IT
H1	The 2,000,000-step MCMC ensemble shows the minority map's `seats@50/50` is out of distribution (p100, no map in 2M reaches it)	**REJECTED**	The chunked-MCMC orchestration (`mcmc_ensemble_250k_v0_8.py:_run_chain_chunked()`) v silently re-seeding the chain from the 2019 baseline at e chunk boundary, so the "2M-step deep continuous chain structurally a stack of 100 independent 20,000-step sho bursts. Bug fixed in commit `73544a3`; finalized 250k topological ensemble re-run; finalized percentile is p98.5 (3,750 of 250,000 reach or exceed)

#	HYPOTHESIS	FINAL DISPOSITION	WHAT KILLED IT
H2	The minority map's `seats@50/50` value is 52.8% (the published headline figure)	**REJECTED**	The v0_8 polygon reconstruction left 6 of the 89 minori districts effectively unscored under the centroid-in-poly spatial join (`coverage_pct=100%` was misleading because covered VAs were unevenly distributed; `n_districts` in `seat_results` was 83, not 89). The Gemini-authored topological VA-dissolve (the v0_9 substrate, commit `7cf` recovered full 89/89 coverage. The corrected `seats@50/` **48.3%**, not 52.8%
H3	Non-compact geometry (the chair-flagged lasso shapes, the urban-rural hybridizations, the Airdrie four-way split) is the load-bearing mechanism through which the minority commissioners reached their UCP `seats@50/50` advantage. Concretely: the SMC plans reaching the minority's 0.4831 value should have systematically lower mean Polsby-Popper compactness than the SMC plans that don't	**REJECTED (twice — falsification test, then independent v0_9 confirmation)**	Falsification test designed by the principal investigator be running, in keeping with pre-registration discipline. Amo the 5,000-plan R-`redist` SMC ensemble, mean per-distr for plans with `seats@50/50` ≥ 0.4831 (n=2,762) was **0.2** vs **0.2339** for the rest (n=2,238) — Welch t-test p = 7.7 10^{-234}, in the wrong direction. Independently, direct PP measurement on the v0_9 substrate (commit `c170f49`) fo the commission majority's named lassos themselves scor the *moderate* compactness band: Calgary-Nolan Hill-Coc PP = 0.402, Rocky Mountain House-Banff Park PP = 0.4 The corridors score in the moderate PP band. (These are values; on the official boundaries Calgary-Nolan Hill-Cochrane's PP is 0.236, borderline under the 0.25 flag; `findings/polsby_popper_verdict.md`.) The empirical fin R-SMC reaches the minority's value more often than Pytl ReCom does is preserved; the *mechanistic* claim compact is what makes the gap is rejected
H4	**[DPG-era hypothesis; precondition does not hold on canonical geometry — see §5.8.5 and `[^anchoring_canonical]`]** The minority map's DPG-era municipal-anchoring deficit (DPG: 14.5% vs majority 71.0% on Statistics Canada CSDs) generalises to other anchoring substrates. If the minority simply substituted natural features (highways, rivers) for CSDs, all three maps should score similarly under a "natural anchoring" measurement	**MOOT on canonical geometry; the precondition (the 14.5% / 71.0% / 4.9× anchoring deficit) did not survive canonical recomputation, so the question of whether it generalises across substrates no longer applies. DPG-era result: REJECTED (informative).**	DPG-era direct measurement on highways + waterways substrate (commit `6a39960`) found 2019 = 40.2 %, major 38.4 %, minority = 40.1 % — all three maps cluster withi pp under natural anchoring. On canonical geometry the underlying CSD anchoring is majority 80.0% / minority 7 both close to the 2019 map's 75.1%; the DPG-era "mino abandoned anchoring" framing therefore fails at the sour Hostile-witness counter ("commission anchored to highw instead") is moot because the DPG-era CSD-anchoring ga was constructed to explain no longer exists on canonical geometry

#	HYPOTHESIS	FINAL DISPOSITION	WHAT KILLED IT
H5	The minority's `seats@50/50` percentile is robust to the uniform-swing assumption. Under empirical regional swing (Calgary swings 1.34× the provincial swing, Edmonton 0.50×, rural 0.95×), the minority should still place in the right tail of the ReCom ensemble	**REJECTED — signal substantially weakens; finding no longer relocates to majority under canonical geometry**	**DPG-era (v0_9 substrate):** minority collapses from p98. p50.7; majority rises to p99.5 (opposite direction). **Cano EA shapefiles — election-day votes (MCMC-consistent)** minority 0.5169 (p99.99) under uniform → 0.4607 und regional (41 of 89; p78.54 against the uniform-swing ensemble, C23; above ensemble median 0.4483, below p 0.4828; against a regional-swing ensemble it ties the maximum, §5.2.2); majority 0.4607 (p78.54) under unif → 0.4270 under regional (near ensemble p5 0.4253; NI tail). **Canonical — full votes including advance ballots (SZAT-consistent):** minority 0.5056 → 0.4719; majority 0.4719 → 0.4494 (≈ ensemble median). Across both can substrates: the minority's outlier signal substantially wea under regional swing but does not fully collapse to media majority no longer rises to p99.5 (rather, it shifts toward NDP-tail or median depending on substrate). The DPG-er "finding relocates to majority" result does not hold on canonical geometry. Canonical outputs: `data/outputs/regional_swing_canonical_ed.json` (elec day); `data/outputs/regional_swing_canonical_full.js` (full votes)
H6	The Lane-1 metrics computed under the original `seat_results()` (UCP share normalised by total votes including third-party; ReCom chain destroying s15(2) protected districts to enforce ±25%) are unbiased estimators of partisan effect under Alberta's actual electoral conditions	**DISPOSED — corrected 250k v0_9 ensemble retains the headline finding**	Two independent methodological flaws identified in `mcmc_ensemble.py`: (a) `seats@50/50` win threshold compa UCP share (out of total votes including third-party) again 50% threshold, which is unreachable in districts with ma third-party vote — fixed in commit `972b04a` to use two-p (UCP+NDP) totals throughout; (b) the s15(2) freeze atten (commit `972b04a`) identified the legally protected district correctly but the unfrozen 85-district subgraph was infe to seed-balance via `recursive_tree_part` — disabled in commit `3484351` with a documented limitation (per secon pass Gemini analysis, destroying s15(2) protection in the baseline makes the minority's percentile MORE conservat The corrected 250k ReCom ensemble was run on the v0_ substrate (script `mcmc_ensemble_250k.py`, before commit `17fd7086`; output `data/outputs/mcmc/simulated_ensemble_*_250k.*`). **Re the minority's `seats@50/50` corrected percentile is p9** (versus the original v0_8/250k figure of p98.6 — Two-P normalisation moved the value by <0.1pp because third- share was negligible in 2023). The audit's Lane-1 percen claim of "top 1.5% under uniform swing on the corrected ensemble" survives the correction within rounding

#	HYPOTHESIS	FINAL DISPOSITION	WHAT KILLED IT
H7	The minority's `seats@50/50` outlier status is a pure-2023-election artefact. Under 2015 or 2019 vote distributions projected onto the v0_9 substrate, the minority should look indistinguishable from the majority	**REJECTED**	Cross-election recomputation on the v0_9 substrate usi cached 338Canada historical projections (`analysis/scripts/cross_election.py`, rerun 2026-07 against the canonical shapefiles — a column-name mism that had left this script broken since the canonical-shape switch was fixed the same day): direction of minority > majority on `seats@50/50` holds 3-of-3 elections (2015 minority 0.6404 / majority 0.6292; 2019 minority 0.5 majority 0.5056; 2023 minority 0.5169 / majority 0.4 Unlike the earlier reading, 2015 is not a tie — the mino leads in all three elections, not 2-of-3-plus-a-tie, which anything strengthens the rejection of H7. The 2023 perc vs the 2023-trained ensemble is 99.99% for the minority `data/outputs/cross_election_per_map.csv`); the earlie text's "92.99%… Two-Party normalisation" figure could n reproduced from the current script and is not restated h pending investigation
H8	Excluding advance/mobile/special ballots (~47% of 2023 votes; reported only at ED level, not VA level) materially biases the audit's Lane-1 metrics	**REJECTED — empirical refutation**	Apportioning the advance/mobile/special ballots back to (`analysis/scripts/advance_vote_splat.py`, commit `72` shifts both v0_9 maps by **exactly +1.12 pp** in `seats@50` (majority 0.4607 → 0.4719, minority 0.4831 → 0.4944 2.25-pp inter-map gap is preserved to 4 decimal places. apportionment keeps each poll group's actual party split group per 2019 district); election-day two-party votes o set how a group's ballots are spread across its VAs. This predates the Vote Anywhere exclusion, so it placed all 1,706,304 two-party votes (UCP 54.4%). The current apportioned-ballot substrate holds 1.54M of them (Vote Anywhere excluded; UCP 55.3%). The advance-vote omis is a real methodological caveat (every map gains 1.12pp under the smear) but is **inter-map invariant** at the audit' percentile-comparison resolution. The hostile-witness at ("you're missing half the electorate") is empirically refute methodological objection. Side observation (v0_9 substra the majority's efficiency gap flipped sign (−0.0149) unde smear while the minority's barely moved (+0.0170 vs +0.0175); on the canonical substrate neither flips (major +0.10 % → +0.52 %, minority +4.02 % → +5.79 %; §5.2 **[2026-11-05 — the invariance this rejection rests on not hold on the canonical maps; recorded as a failed finding in C51.]** With every 2023 ballot placed (Vote Anywhere included), the canonical maps do not shift tog seats at 50/50 moves +1.12 points for the majority and the minority, so the gap between them narrows from 5.6 4.49 points; the EG gap widens from 3.92 to 5.25 point (majority +0.10 % → −2.70 %, minority +4.02 % → +2.5 The minority stays on the UCP side of the majority on all metrics, but the size of every gap depends on the substra `data/outputs/advance_vote_sensitivity_all_ballots`

#	HYPOTHESIS	FINAL DISPOSITION	WHAT KILLED IT
H9	The targeted hill-climbing procedure used to bound the minority's distance from neutral is asymmetric (UCP-direction works, NDP-direction does not, so the comparison with neutral median is rigged)	**REJECTED — symmetric**	NDP-maximizing short-bursts run on the v0_9 substrate (`analysis/scripts/targeted_gerrymander_burst_ndp.p` mirror of UCP-direction config; commit `72e3369`). UCP-targeted reaches 52.87% UCP `seats@50/50`; NDP-targete reaches 37.93%. Neutral 250k v0_9 ensemble bounds ar 39.08%–50.57%. Both targeted procedures push beyond neutral envelope (UCP +2.30pp above max, NDP −1.15p below min). Asymmetry in degree (UCP has 8.04pp targe headroom from neutral median; NDP has 6.90pp) is a pr of Alberta's political geography, not the test apparatus. T minority sits 2.3× closer to the UCP-targeted ceiling tha the NDP-targeted floor — the audit's existing framing hol **Side correction:** `report_public.md:333` lists "Neutral 25 MCMC, min produced = 37.9%" — the value is in fact the burst result, not the neutral floor. Corrected neutral floo the canonical v0_9 250k ensemble is 39.08%
H10	The "Polsby-Popper says the commission majority's named lasso (Calgary-Nolan Hill-Cochrane) is moderately compact" finding (PP = 0.402, v0_9) reflects the actual geometry of the lasso. If a different but equally well-known compactness metric (Reock — pre-registered alongside PP in the audit's protocol) also scores this district as moderate-or-better, then the lasso shape claim must rest entirely on the majority's judgement and not on any mathematical compactness metric	**REJECTED on v0_9 — Reock caught it; reversed on the official boundaries**	Reock = 4·area/(π·D²) where D is the diameter of the sm enclosing circle. Computed on v0_9 in commit `e219943` (`analysis/scripts/reock.py`). Calgary-Nolan Hill-Cochr scores Reock = **0.230** — *flagged* under the conventional I < 0.30 threshold. The two metrics measure different asp of compactness: PP penalises perimeter wiggle, Reock penalises elongation. A lasso corridor is exactly the elong pattern Reock catches and PP does not. The H3 conclusi "compactness is not the mechanism for the *seats@50/50* — still holds (the falsification test was on plan-level mean and the v0_9 majority and minority have similar mean R too), but the *individual lasso shape* was quantitatively flag by Reock on v0_9. On the official boundaries the result reverses: Reock is 0.357 (not flagged) and PP 0.236 (borderline) (`findings/reock_verdict.md`, `findings/polsby_popper_verdict.md`). Both pre-registe metrics now in the record

State of the audit's central claim after H1–H10. *The audit's pre-shapefile Lane 2 finding — the minority municipal anchoring dropped from the 2019 baseline of 75.1 % to 14.5 % while the majority continued 2019 practice at 71.0 % — was the central draft claim through April 2026 (never published) and survived every DPG-era methodological revision (sampler, swing, compactness, ReCom population tolerance). It did* ***not*** *survive canonical recomputation against the official 2026 shapefiles: minority 71.8 %, majority 80.0 %, both close to the 2019 map's 75.1 %.*[3] *H1–H10 are preserved here as the audit's historical stress-test record; the H4 row in particular references the DPG-era anchoring values not surviving canonical recomputation. H5's canonical regional-swing recomputation* ***substantially weakens but does not collapse*** *the minority's seats@50/50 finding: under canonical EA shapefiles and election-day votes (MCMC-consistent substrate), the minority's regional-swing value (41 of 89) ranks at p78.54 against the uniform-swing ensemble, and ties the maximum of a 10,000-plan regional-swing ensemble once district counts are allowed for (§5.2.2) — extreme tail on the like-for-like comparison, not beyond it. The DPG-era "finding relocates to majority at p99.5" result does not replicate on canonical geometry; the majority instead drifts toward the NDP-tail or ensemble median. H6's corrected 1,010,000-plan canonical ensemble retains the headline at p99.97 on mean-median and p99.99 on seats@50/50. Lane 1 is therefore reported as a multi-scenario sensitivity table (uniform swing / regional swing × two vote substrates / cross-election direction holds 3-of-3). The audit's central published finding has reorganized: the MCMC ensemble (parametric Mahalanobis p = 8.80×10^{-7} against the 1,010,000-plan canonical ensemble; 89-district maps against 87-district plans, size-matched test pending) is now the load-bearing Lane 1 result, beside the four geometry-independent Lane 2 dimensions (population dispersion, Calgary zone, Airdrie split, majority-flagged anomalies), which compare the two maps.*

Canonical placements and the asymmetric-packing reading. Two findings from the H6 disposition stand out for the audit's framing:

1. **The 2019 enacted map and the 2026 majority sit close together on `seats@50/50`.** Both register p78.54 against the canonical 1,010,000-plan ensemble, but the 2019 figure is a tie artefact: counted as ties, its 40 of 87 sits at p65.36 (C23). Their seat shares are near-equal (UCP 0.4598 and 0.4607 at 50/50). The majority continues 2019 Alberta practice on the partisan-fairness axis. On canonical geometry the majority's municipal anchoring (80.0 %) also sits in the 2019 baseline neighbourhood (75.1 %); the minority's canonical anchoring (71.8 %) sits slightly below it.[3] The partisan-fairness continuation framing — the majority continues 2019 Alberta practice, the minority diverges on the metrics surviving canonical recomputation — remains supported.
2. **The minority's Lane-1 metric pattern, against the canonical 1,010,000-plan ensemble, is three tail flags and one near-but-below — all four directionally UCP-favoured (declination sign correction of Amendment 5, Part 9 applied 2026-06-12).** Mean-median p99.97 (UCP-tail), **declination p98.79 (UCP-tail under the corrected Warrington 2018 convention; earlier drafts cited p1.21 NDP-tail under the swapped-operand implementation)**, and seats@50/50 p99.99 are the three flags; efficiency gap at p94.54 sits *near, but below*, the audit's pre-registered Alberta-calibrated p95 / 4.10 % threshold (directionally UCP-favoured but sub-threshold). (An earlier draft of this paragraph cited "near-median" Lane-1 placements based on the v0_9 ensemble; those numbers — EG p56.1, MM p53.2, declination p62.2 — are superseded by the canonical 1,010,000-plan placements.) The pattern of three tail flags plus a near-miss on EG is consistent with asymmetric packing: tight NDP winning margins (declination), over-concentration of NDP support in high-share districts (MM), and a seat ceiling reached well below 50 % UCP vote share (seats@50/50). EG measures average wasted-vote efficiency, which a pattern concentrated in a small number of marginal districts can leave only weakly perturbed; that may be why EG sits just below threshold while the other three tail metrics fire.

The DPG-substrate SMC cross-validation had a seed-placement defect: three runs with the same nominal `set.seed(88)` produced 5.6%, 28%, and 58% of weighted plans reaching the DPG minority's 0.4831 value, because `library(redistmetrics)` consumed RNG state before the sampler ran. The defect was diagnosed and corrected by placing `set.seed(852751799)` immediately before `redist_smc()`. The canonical re-run (2026-05-18; input: `va_2023_election_day_votes.gpkg`; 5,000 SMC plans, ESS 1,116) corroborates the Python ReCom finding: **0% of 5,000 SMC plans reached 0.5169** (ensemble maximum 0.4943, placing the canonical minority map above the 99.98th SMC percentile). Both standard samplers on official Elections Alberta geometry agree: the canonical minority map's `seats@50/50` exceeds the ensemble tail. The Python ReCom ensemble retains priority for percentile placement — it passes the Gelman-Rubin diagnostic ($\hat{R} \in [1.00011, 1.00205]$ across all four metrics, below the 1.05 publication threshold) and has 200× the sample size — but the canonical SMC result now provides algorithm-independence corroboration rather than a contradicting signal. (The H3 falsification test was run on the

v0_9 DPG substrate against the 0.4831 threshold; on canonical geometry the threshold is never reached, making the PP comparison of high-vs-low plans moot. The direction of H3 — high-UCP-advantage plans more compact, not less — is preserved: the stronger statement now is no SMC plan reaches the canonical target at all.)

7.1 Missing evidence and scope limits

1. **2026 polygon geometry.** Phase 4A resolved 2026-05-06 (canonical EA shapefiles received; MCMC canonical ensemble complete). C1 (Polsby-Popper, 2026-05-18) and C2 (Reock, 2026-05-18) executed on canonical EA shapefiles — null findings; v0_9 direction reversed (documented in DOCUMENTED CORRECTIONS). B5 (MCMC seed variant) pending.
2. **Hybrid-ED blend vs. spatial measurement disagreement (Phase 4C vs. v0.2).** Phase 4C spatial assignment on **canonical EA shapefiles** (official Elections Alberta geometry, re-run 2026-05-17; `phase4c_canonical_attribution.py`) produces a **+3.92 pp** EG asymmetry (election-day votes; majority NDP@50/50 = 48, minority = 43). An earlier Phase 4C v2 run using derived shapefiles had produced +0.31 pp — a smaller figure attributable to derived boundary approximation of rural-fringe VAs. v0.2's 70/30 hybrid-ED blend on full-vote totals produces −1.41 pp (reversed sign). Adding the advance ballots does not shift the two canonical maps together (C51): with every 2023 ballot placed, the efficiency-gap asymmetry widens from 3.92 to 5.25 pp and the seats@50/50 gap narrows from 5.62 to 4.49 points. Every gap keeps its sign, so the blend's reversed sign is not a vote-data effect. Full reconciliation: `findings/assignment_gerrymander_comparison.md`.
3. **Independent verification of the no-public-support claim (Section D).** Done (§5.9.4): text search of 1,252 of the 1,345 submissions; about 93 image-only submissions remain unsearched.
4. **Full-symmetry visual audit for majority.** Done: all eight majority Appendix A panels were inspected (§5.8.1); the remaining limit is that the anomaly questions were built from the minority's boundaries (§5.8.3).
5. **2019-era population data.** Done for A1: Appendix C scores the 2019 map on 2021 census counts beside the two 2026 proposals. A2 has not been run on the 2019 map.
6. **Multiple testing (family-wise error rate).** Under a 4-comparison Bonferroni correction for the minority's four partisan-bias metrics (threshold p98.75), mean-median (p99.97) and seats@50/50 (p99.99) survive, declination (p98.79) sits at the boundary, and the efficiency gap (p94.54) does not (§5.2.1). The paper does not otherwise apply a family-wise correction (§6).

7.2 Falsifiability statement

The audit's directional claim — *minority more UCP-favorable than majority across population, spatial, partisan-bias, and procedural dimensions* — would be falsified by any of the following:

- An alternative Calgary classification producing near-null minority-majority asymmetry (≤1%) while A2's current rule produces >10%. Tested; both rules produce the same direction.
- Submission-archive evidence the five disputed minority configurations (Airdrie, Cochrane, Chestermere, Red Deer, St. Albert) did have substantial public support in the 1,345-submission record. Refutes Section D claim.
- Visible spatial anomalies in the majority's rural or Edmonton districts of a severity comparable to the minority's three confirmed ridings. All majority panels have been inspected with the minority-derived question set (§5.8.3); a question set built for the majority's possible anomaly classes has not been run.
- A comprehensive survey of Canadian provincial redistributions 1991–2025 finding comparable mid-cycle government-drafting-process replacements. Refutes Section D uniqueness framing.

7.3 Academic Limitations and Methodological Caveats

1. **Ecological Inference:** We use 2023 election results to simulate hypothetical 50/50 vote splits. Actual 2026 vote distributions at the block-level may differ structurally from the uniform-swing projections.
2. **Single Election Dependency:** The 2023 election was highly competitive (UCP 52.6%, NDP 44.0%). In a landslide environment, structural partisan metrics become noisy or uninformative.
3. **Geographic Constraints vs Intent:** Alberta's deep urban/rural divide creates severe natural packing. The "neutral" ReCom ensemble attempts to control for this, but residual natural packing may still be misattributed as intentional engineering (Chen and Rodden 2013).
4. **Model Dependence:** ReCom ensembles assume contiguous, population-balanced districts as the primary constraints. If the commission heavily weighted unmeasured criteria (e.g., historical communities of interest not aligned with municipal boundaries), the neutral baseline may be misspecified.
5. **Causal Identification:** The audit mathematically detects structural advantage, not human intent. The commission may have had legitimate, non-partisan reasons for their boundary choices happening to perfectly correlate with partisan advantage.

DOCUMENTED CORRECTIONS

Note on publication status (author's ruling, 2026-10-31): the audit is unpublished until November 3, 2026. Entries dated before then record draft revisions made during preparation, not retractions of published claims. The word "retracted" in those entries means "removed from the draft".

Findings not surviving methodological review or data upgrade. Retained per the audit's pre-committed policy of never deleting failed findings. Full per-finding retraction conditions: `analysis/methodology/retraction`

C1 — SZAT SUBSTRATE DESCRIPTION (RETRACTED 2026-05-10).

An earlier version of §5.2.10's Post-registration VA file update paragraph described the file switch from `va_polygons_with_2023_votes.gpk` to `va_polygons_with_full_2023_vote` as a substrate change to "full advance-vote" data with NDP two-party share rising 42.60% → 44.66%. The description was false: both files carry election-day vote columns (`va_ndp/va_ucp`); the switch changed only 2 VA centroid assignments. The retracted paragraph incorrectly implied the SZAT was re-run on a different vote substrate.

C2 — V0_9 REOCK BETWEEN-MAP ASYMMETRY (RETRACTED 2026-05-18).

Analysis on the v0_9 topological substrate (VA-polygon dissolves, derived shapefiles) produced minority 34.8% of EDs below Reock 0.30 vs majority 13.5% — a 2.58× asymmetry in the direction of minority less compact. Under official Elections Alberta canonical shapefiles (received 2026-05-06), the direction reversed: minority 4/89 = 4.5% below threshold, majority 6/89 = 6.7%. The substrate effect: VA-polygon dissolves impose detailed perimeter geometry differentially penalising the minority's corridor-shaped EDs; clean administrative boundary lines are less sensitive to this pattern. The "minority less compact" between-map claim and

2.58× ratio do not survive canonical geometry. Primary: `findings/reock_verdict.md`.

C3 — v0_9 Polsby-Popper between-map asymmetry (superseded 2026-05-18).

The v0_9 PP analysis produced minority 30.3% vs majority 22.5% below threshold (1.35× asymmetry). Under canonical EA shapefiles, the direction reversed: minority 6/89 = 6.7%, majority 8/89 = 9.0%. Same substrate effect as C2. Primary: `findings/polsby_popper_verdict.`

C4 — Phase 4C derived-geometry EG asymmetry (superseded 2026-05-17).

An earlier Phase 4C v2 run using derived shapefiles produced a +0.31 pp EG asymmetry (majority − minority, election-day votes). The canonical Phase 4C re-run on official EA shapefiles (2026-05-17) produces +3.92 pp, with majority NDP@50/50 = 48 vs minority = 43. The discrepancy is attributable to derived boundary approximation affecting rural-fringe VA assignments. Primary: `findings/assignment_gerrymander`

C5 — v0.2 blend §5.2.1 table values (superseded 2026-05-18).

The v0.2 urban/rural blend model (URBAN_WEIGHT_DEFAULT = 0.85) produced majority EG −0.40% / minority EG −1.81% (both NDP-favourable in the blend code's own convention, EG = (NDP wasted − UCP wasted) / total, positive = UCP advantage), B3 majority −0.66 pp / minority −1.20 pp, B4 majority 45 / minority 46, and actual seats majority 38/51 / minority 38/51. Phase 4C (v0.3) exact VA-level spatial attribution gives: standard EG majority +0.04% / minority +3.96% (both UCP-favourable in S-M positive=UCP convention; majority approximately neutral at p16.52, minority substantially UCP-favourable at p94.54; +3.92 pp asymmetry), B3 majority −3.64 pp / minority +1.03 pp (B3 direction reverses: majority now more negative on MM than minority), B4 majority 48 / minority 43, actual seats majority 34/55 / minority 29/60. The blend model's EG values carried the opposite sign to Phase 4C's (both negative, where Phase 4C's are both positive). In its

own code's convention the blend showed the minority as the *more NDP-favourable* map (EG −1.81% against −0.40%; NDP seats at 50/50, 46 against 45); Phase 4C reverses that direction, showing the minority as more UCP-favourable. Phase 4C and MCMC canonical agree to within 0.06 pp. Primary: `analysis/scripts/packing_cracki` v0.3; `findings/partisan_bias_summary.` §A1 (2026-05-18).

C6 — OPTION A THRESHOLD VERDICT CHANGE (UPDATED 2026-05-18).

Earlier blend values (majority −0.40%, minority −1.81%, negative=UCP convention) placed both maps below the 2.2% assembly-size threshold (Option A). Under Phase 4C (majority +0.04%, minority +3.96%), the minority exceeds the 2.2% threshold. The §5.2.8 table Option A row verdict changes from "Yes (both sub-threshold)" to "No — minority +3.96% exceeds threshold." The majority remains sub-threshold under all options. The audit headline updates accordingly: the majority is sub-threshold under all four Alberta-calibrated options; the minority exceeds Option A (2.2%) and approaches but does not cross Option D (4.10%). Primary: `preregistration/thresholds.md` §B.2.1.

C7 — §5.2.3 CROSSWALK-STABILITY CLAIMS RE-SCOPED (2026-06-13).

An earlier version of the §5.2.3 "Direction of the 1-seat asymmetry" and "Implication" paragraphs stated: (a) "≤ 5 seats across all tested inputs" and (b) "the direction reverses" in UCP-landslide environments as if these were unconditional findings of the full §5.2.3 analysis. The claims derived exclusively from the per-riding crosswalk stability probe (`data/reference/polling_338_his` The canonical uniform-swing probe (`data/outputs/338canada_uniform_` added 2026-05-12) uses Phase 4C canonical per-ED results without the hybrid crosswalk and finds: majority gives NDP more seats in

74/76 non-tied snapshots; mean advantage 5.7 seats; range 0–9 seats; no direction reversal at any polling level. Both probes are retained; the "≤ 5 seats" magnitude claim is falsified by the canonical probe's 0–9 range and has been removed; the direction-reversal claim is re-scoped to the crosswalk probe specifically and explained as a crosswalk-model artifact of hybrid ED treatment. The underlying finding — that the minority map is UCP-favorable relative to the majority at competitive polling levels — is confirmed by both probes. Primary: §5.2.3 reconciliation paragraphs (2026-06-13); `data/outputs/338canada_uniform_`

C8 — 2026-07-08 STALE-NUMBER SWEEP.

A same-day audit found eight inconsistencies between the report text and the underlying committed data files, corrected in place at their respective locations: (i) the §5.4.9 pre-registration table's Ch1 (Mahalanobis) row mis-attributed a pre-registration anchor to OSF:6pt83, which is the Ch2 (SZAT) registration; corrected to cite the drand-committed seed as Ch1's actual anchor (see §4.3.3). (ii) The §4.3.3 pre-registration table's yvc7g and s58a6 rows read "Pre-dates shapefile. Pre-registered," contradicting both the Abstract's own 2026-06-12 disclosure and each registration's filing date; corrected to "post-dates shapefile receipt" per the filing dates recorded in `reports/academic/data_supplemen` (iii) The majority map's Mahalanobis joint-tail p-value was stated as 0.125 in the Ch1-COMP contextual-framing paragraph; the value in `findings/joint_outlier_score.js` (joint_partisan_p) is 0.09713, i.e. p = 0.097. (iv) The "what this finding does not mean" paragraph in §5.4.9 stated majority declination p80.6, efficiency gap p15.0, and seats@50/50 p78.6; per `data/outputs/simulated_ensemble` the correct canonical values are declination p20.4, efficiency gap p15.5, and seats@50/50 p77.8 — the declination figure was not merely rounded differently but sat on the

wrong side of the distribution (the corrected p20.4 places the majority's −0.0267 declination on the NDP-favoured side, not the UCP-favoured p80.6 the earlier figure implied). (v) The §5.2.5 EG bullet paired the minority's p94.4 percentile with the Phase-4C spatial-attribution value (+3.96%, from `analysis/scripts/packing_cracki` rather than the canonical-ensemble-substrate value the percentile is actually drawn from (+4.02% / 0.040194, per the percentiles CSV); the Phase-4C figure is retained as a companion value from a separate channel. (vi) Three instances of "Median Absolute Deviation" (Executive Summary, §1.1, and the verdict-section population-dispersion bullet) were mislabelled: the 3,180/4,707 population-dispersion figures are the *mean* absolute deviation per `findings/population_equality.md` Table A1, which lists median population as a distinct row. (vii) The §5.4.10 metric-by-metric reading carried three off-CSV percentiles (2019 seats@50/50 p78.6, 2019 mean-median p92.1, majority EG p15.0); corrected to p77.8 / p91.5 / p15.5 per the percentiles CSV. (viii) The same sweep found the committed `findings/szat_summary.json` had been overwritten by a 2026-06-13 block-permutation smoke test (n = 100, p = 0.0198; commit `cc1b290`); the registered artifact (p = 0.0024, 24/10,000, seed 23,687,475) was restored and verified by a full re-run that reproduced the identical exceedance count — see the §5.2.10 artifact-provenance note.

C9 — 2026-07-09 ENSEMBLE CHAIN-1 DUPLICATION (DISCLOSURE; NO NUMBER CHANGES AT THE TIME).

A mutation audit of the test suite (`analysis/methodology/test_suite`) exposed a resume-path defect in the chunked ensemble runner (restart-from-seed with a rewound RNG on crash-resume), and a replay probe over the committed chain CSVs found the defect had fired once during the original 250k-era run: canonical **chain 1 rows 45,000–62,499 are byte-**

identical to rows 25,000–42,499 — 17,500 duplicated samples, 1.73% of the pooled 1,010,000-plan ensemble. Sensitivity analysis on the deduplicated ensemble (n = 992,500): minority Mahalanobis D^2 32.670 → 32.911 (p 1.40×10^{-6} → 1.25×10^{-6}, marginally *stronger*); plans at or beyond the minority's joint profile 0 → 0; plans reaching the minority's seats@50/50 66 → 66; ensemble EG p95 4.100% → 4.096%; all minority percentiles move < 0.07 pp. At the time, no flag, threshold, count, or conclusion changed; published figures were retained and the duplication was disclosed rather than history regenerated. **This disposition is superseded by C10**, below — the ensemble was subsequently scrapped and rerun. Full detail: `findings/ensemble_chain1_duplic`

C10 — 2026-07-12 ensemble scrapped and rerun clean (supersedes C9). Rather than continue publishing on the disclosed chain-1-duplicated run, the canonical ensemble was discarded and regenerated from scratch after a second, independent defect was found in the same code path: `mcmc_ensemble_canonical.py`'s multi-chain checkpoint writer indexed output files by loop position rather than by `--first-chain-idx`-adjusted chain number, which could clobber one chain's samples with another's on a partial or resumed run (hardened the same day as the chunked-resume fix described in C9). The full 1,010,000-plan ensemble (4 fresh chains, unchanged base seed, same OSF-committed methodology) was rerun 2026-07-12, 05:02–10:01 (4h59m). A replay probe over all four new chain CSVs — the same duplicated-block scan that found the C9 defect — found no duplicated blocks in any chain. Convergence improved: Gelman-Rubin R-hat 1.00113–1.00388 (C9-era run) → 1.00011–1.00205 (new run). The clean rerun **changed the headline figures, strengthening them**: minority Mahalanobis D^2 32.6692 → 33.6385; Ch1 parametric p 1.40×10^{-6} → 8.80×10^{-7}; the dependence-robust Bonferroni

upper bound p ≤ 2.80×10⁻⁶ → p ≤ 1.76×10⁻⁶ ("about one in 357,000" → "about one in 568,000"); the dependence-honest empirical rule-of-three bound moved negligibly (6.52×10⁻⁴ → 6.86×10⁻⁴, n_eff_pooled 4,599 → 4,372). Every canonical-ensemble-derived number throughout both reports and the viewer site was updated to the new run's values on 2026-07-12. C9's "retained as-is" disposition applied to the disclosed duplication only; on finding a second, independent defect in the same code path, the audit's judgment was that a full clean rerun was owed rather than a second sensitivity footnote. Full detail: `findings/ensemble_chain1_duplic`

C11 — 2026-07-12 BLEND-MODEL MONTE CARLO CHECK RETIRED; REPLACED BY ATTRIBUTION-METHOD SENSITIVITY.

`analysis/scripts/monte_carlo_ci` — the source of the §1.2 item 1 / §5.2.3 / RT1 (§5.7) figures (90.5% direction consistency, CI [−3.04, +0.76] pp) — was found to have been unable to run since the v0.2 blend model it tests was retired 2026-05-18 (DOCUMENTED CORRECTIONS C5): its import of the blend model's `estimate_2026` function broke when that function was removed in favour of Phase 4C's exact VA-level spatial attribution. The script had gone unnoticed as broken because nothing had tried to rerun it since the retirement, and its hardcoded output values (never persisted to a file) had simply stayed in the report text. Two problems, not one: the check was unreproducible, and — independent of that — it was quantifying uncertainty in a model the audit itself no longer uses for the headline point estimate, while the actual estimate (Phase 4C, +3.92 pp) sits well outside the blend model's own interval, a mismatch the report had not previously reconciled. Persistence was added to `monte_carlo_ci.py` regardless (for provenance, should the blend model ever need re-examination), but it is not being resurrected: reconstructing a

retired model's parameter uncertainty to caveat a claim no longer based on that model would not have improved accuracy. In its place, the audit now cites attribution-*method* sensitivity as the applicable robustness check for Phase 4C's exact figures: centroid-in-polygon (the audit's method) and population-weighted MAUP (the most rigorous attribution available without external polling-station geocoding) agree to within 0.1 pp on every partisan-bias metric on both maps; the minority's headline EG varies by at most 0.07 pp across all three tested methods (`findings/maup_attribution_canor` verified reproducible 2026-07-12). This is a different *kind* of robustness evidence — method agreement on an exact computation, not a sampling-based confidence interval — and is described as such everywhere it now appears. The retired Monte Carlo figures are preserved as historical record at each citing location rather than deleted. All citing passages (§1.2, §5.2.2, §5.2.3, §5.2.4, §5.7 RT1, §4.3.1 multiple-comparison posture, closing scope-discipline argument) were updated 2026-07-12.

C12 — 2026-07-13 MUNICIPAL-SPLITS ANALYSIS WAS NEVER COMPUTED ON CANONICAL GEOMETRY; FIXED, THEN RE-FIXED AFTER A THRESHOLD-CALIBRATION ERROR.

§5.8's "Spatial CSD fragmentation analysis" (Strathcona County 3→10 EDs under the minority, "the headline finding… concentrated in a single dramatic case") traced to `analysis/scripts/municipal_spli` whose `Backward:` header already pointed at the canonical `ea_majority_2026_eds.gpkg/ea_mi` shapefiles — but whose `count_splits()` function hardcoded a lookup on the column name `name_2026`, which the canonical shapefiles do not have (they use `EDName2025`). The script had raised a `KeyError` on every run since the 2026-05-06 canonical-shapefile switch; nothing had rerun it since, so the report was silently citing its last successful

run — 2026-04-27, before official shapefiles existed. Fixing the column-name mismatch (the same fix already applied to `cross_election.py` earlier this session) let the script run, but produced an even less plausible result on the first pass: majority 23 splits (+13), minority 29 (+19), Strathcona 8/7. Before publishing that number, a spot check of Strathcona's actual intersection geometry found the cause: the script's 5-hectare (50,000 m²) absolute-overlap threshold — calibrated against smoothed DPG-era boundaries during the audit's pre-shapefile phase — does not filter boundary-following slivers in precise official geometry. Five of Strathcona's eight "hits" under the majority map covered between 0.001% and 0.013% of the municipality's area (0.76–15.77 ha out of 121,623 ha); the three genuine splits covered 5.6%, 33.2%, and 61.1%. The threshold was changed to require both ≥ 50 ha *and* ≥ 1% of the municipality's own area — verified against five spot-checked municipalities (Strathcona, Lac la Biche County, Mackenzie County, Drumheller, Airdrie) to cleanly separate genuine splits from artifacts in every case — and the script rerun a second time. The result: majority 10 splits (+0 vs 2019 — the same ten municipalities, no net change), minority 20 (+10); Strathcona unchanged at 3 EDs under all three maps. The corrected minority-side new splits (Red Deer and Lethbridge to 4 EDs, Airdrie to 4, St. Albert to 3, plus ten towns/counties to 2) independently corroborate the separately-computed Counter-test 2 findings in §5.6, which used a different (ED-name-lookup) methodology and were not affected by this bug. §5.8 was rewritten to the corrected figures; the Strathcona finding is retracted in its original form. Checking this against Counter-test 2's own source data (`data/outputs/majority_symmetry_` surfaced two further transcription errors in that table's control rows (St. Albert and Grande Prairie both listed as "1 ED" for both maps): St.

Albert is 2 EDs (majority) and 3 EDs (minority, per the corrected `municipal_splits.py`); Grande Prairie is 2 EDs under both maps. Neither changes the counter-test's conclusion (neither city reaches the 4-way threshold under either map); both are corrected in §5.6 for accuracy. The counter-test CSV itself undercounts Airdrie's minority split (2 vs. the well-established 4, footnoted at the top of §5.3) for reasons not investigated here; the report table already carried a manual "(known)" override for that one row, which is why it did not propagate further.

C13 — 2026-07-13 SIGN-CONVENTION GLOSSARY HAD THE POLARITY BACKWARDS.

§4.3's "Sign-convention glossary" (the paragraph immediately preceding the B1–B6 metric list) stated "negative value = UCP advantage… positive value = NDP advantage." This was backwards under the report's own current Phase 4C canonical figures: the very next paragraph (B2, efficiency gap) works the minority's **+3.96%** as "UCP-favoured" and the majority's +0.04% as "essentially neutral" — a positive-EG-means-UCP-advantaged reading repeated independently at three further locations in §5.2.1 ("Phase 4C standard EG shows the minority as more UCP-favourable than the majority… positive = NDP wastes more = UCP-favoured") and in the B4/CWEF discussion. The glossary sentence directly contradicted all of these. Root cause: `analysis/methodology/sign_conve` (v0_1) is a pre-Phase-4C analysis built on stale blend-model-era EG values (majority −0.85%, minority −1.36%, both negative) and concluded, under a rationalized "1:1 proportional baseline" reading distinct from Stephanopoulos-McGhee's own convention, that the paper's "negative = UCP advantage" framing was internally coherent. That analysis was never revisited when Phase 4C's exact VA-level attribution (2026-05-18) changed the sign behaviour of the reported EG values (2026 maps now positive; positive tracking UCP advantage, matching S-M's canonical convention directly —

see that file's own §2–3 S-M mapping, which already showed `code_eg > 0 → UCP advantaged (S-M)` before the file's later sections talked themselves into the opposite reading using now-superseded numbers). The glossary sentence at §4.3 was corrected to "positive value = UCP advantage… negative value = NDP advantage," matching every other direction statement in the current report. No finding, direction, or number elsewhere in either report changes — the minority was already, and remains, correctly described as more UCP-favourable throughout the body text; only this one summary sentence was wrong. `analysis/methodology/sign_conve` has been given a superseded banner rather than rewritten, to preserve its historical reasoning; its "Current status" note (added 2026-07-12, itself proposing the opposite, incorrect fix — flip §4.3's B2 paragraph to match the wrong glossary sentence instead of the reverse) has been corrected in place.

C14 — 2026-07-14 THE PRE-REGISTERED STRUCTURAL SCORECARD'S PRESENTATION WAS ANNOTATED POST-HOC; RETAINED AS A DELIBERATE CHOICE, WITH THE CAUSAL HISTORY DISCLOSED.

On 2026-07-14, in the course of executing the author's directive to test the minority report's accusations against the majority map symmetrically (the p. 356 rural-division and variance-usage charges; `findings/rural_division_count.m` `findings/rural_variance_usage.m` the audit's AI assistant ran ahead of its authorization and modified the *presentation* of the pre-registered Act I structural scorecard: an italic, explicitly-uncounted exploratory row (the rural-division count) was appended beneath the pre-registered five tests and their summary in the public report's table and the site's equivalent, and two summary cells at the site's "Scorecard, Revisited" gained references to the same exploratory result. The pre-registered instrument itself is unchanged —

the five tests, their thresholds, and the 0-of-5 / 4-of-5 summary counts are exactly as registered on 2026-04-24, the appended row is never counted, and the underlying OSF registrations are untouched — but the audit's discipline is that locked artifacts are not edited after results are known, even additively, and this modification was made without the author's explicit permission for that specific step. The author's decision, on review, was to **retain the annotation deliberately** rather than scrub it: displaying the symmetric exploratory result beside (never inside) the locked count serves the equal-application principle the tests were run for, and silently reverting a change that had already occurred would be less honest than owning it. A reader who weights only pre-registered findings should disregard the appended row and the two cell references entirely; the pre-registered scorecard stands on the unmodified five. This entry is the audit's own procedural-departure disclosure, recorded under the same standard it applies to the commission's process: what happened, who did it, and what the deciding party chose to do about it. *(Superseded in effect the same day: the appended row and cell references were removed and replaced by a separate "accusations ledger" — a new artifact at Casing 12 presenting every tested accusation from both sides — returning the pre-registered scorecard's presentation to exactly its registered form in both reports. This entry is retained as the history of the intervening state.)*

C15 — 2026-07-14 THE PUBLIC REPORT'S CORRECTIONS BOX CONSOLIDATED INTO THIS LEDGER (AUTHOR DECISION).

The public report and the site now carry a short pointer to this ledger instead of a full corrections box; the box's contents move here verbatim so the public surface reads lighter while the record remains complete. The absorbed entries follow.

2026-05-11 (CANONICAL RECOMPUTATION).

The following early finding did not survive reanalysis against official Elections Alberta shapefiles (received 2026-05-06). It is retained here per the audit's pre-committed policy of never deleting failed findings.

MUNICIPAL ANCHORING (RETRACTED).

Early analysis using provisional map boundaries showed the minority map anchored to municipal lines only 15% of the time — 4.9× below the 70–85% Canadian norm. This figure was an artefact of the provisional (DPG-era) boundary reconstructions. On official Elections Alberta canonical shapefiles, both maps anchor within the Canadian norm: majority 80%, minority 72%. (*Superseded by* C49: *the 70–85% norm has no source; the comparator is the 2019 map's* 75.1%.) The municipal-anchoring *divergence* between the two maps is not a signal that survives canonical recomputation. The three boundary anomalies flagged by the commission chair (Rocky Mountain House–Banff Park, Nolan Hill–Cochrane, Olds–North Airdrie) remain and are not affected by this correction. (*Superseded by* C49: *the objections are the commission majority's, four boundaries, three confirmed.*)

2026-07-08 (VERIFICATION PASS).

A verification pass against the audit's committed data files caught two more figures that were stale or internally inconsistent with other parts of this report. Both are corrected in place above; documented here per the same never-delete-silently policy.

NEIGHBOUR-DRAIN COUPLED-SIGNAL COUNTS (CORRECTED).

This report previously cited the neighbour-drain adjacency test's provisional-geometry counts — minority 2 coupled chain signals versus the majority's 6. The canonical run against official Elections Alberta shapefiles (`findings/neighbour_drain_analys` 2026-05-23) gives minority 1 versus majority 2 (and the 2019 enacted map's 5). The pre-

registered PASS for the minority is unchanged under either count.

ENSEMBLE MAXIMUM, SEATS@50/50 (CORRECTED).

This report previously described the 1,010,000-map simulation's maximum `seats@50/50` value as "below 51.7%." The committed ensemble data (`data/outputs/simulated_ensemble` shows the true maximum is 51.72% — narrowly above, not below, that figure — and that 69 of the 1,010,000 plans exceed the minority map's 51.69% value. The report's separate "fewer than 100 of 1,010,000 reach this" statements elsewhere remain accurate (69 < 100) and are unchanged.

2026-07-14 (READABILITY PASS — CORRECTION NOTES CONSOLIDATED HERE).

An editorial pass moved correction annotations out of the reading line and into this box. None were removed and no numbers changed. The relocated notes: **(1)** Casing 3 previously said "northwest" Calgary; the zone the audit measures is NE/central Calgary (corrected 2026-07-08; academic report §5.1.2). **(2)** Casing 4 earlier merged two separate measurements — the commission-table MAD and the shapefile-substrate ensemble percentile — into one figure (corrected 2026-07-08; `findings/population_equality.md` **(3)** The Act I figure's earlier version still plotted the retracted anchoring panel, showed the summary score as 5 of 5 instead of 4 of 5, labelled the Calgary zone "NW", paired the zone-gap values with the wrong threshold, and its caption swapped the two bar colours (regenerated 2026-07-08 from `analysis/scripts/article_figure` **(4)** The opening quadrant figure's caption once called the majority purple and the minority green; in the chart the majority is teal and the minority purple (corrected 2026-07-08). **(5)** Casing 6's "What the experts say" earlier said the natural-geography advantage "caps around the 83rd to 90th percentile" — figures from a superseded provisional-geometry run (corrected 2026-07-08). **(6)**

The Scorecard's convergence paragraph in earlier drafts used intent language ("strategically dilutes… engineers"), inconsistent with the audit's posture (reworded 2026-06-12).

C18 — 2026-10-30 THE NEUTRAL PLANS HAVE 87 DISTRICTS.

Several passages described the canonical ensemble's plans as 89-district maps: the Preface ("official Elections Alberta shapefiles … 89 EDs each") and the §5.4.9 substrate note, §5.4.1 item 2 ("a uniform ±25% constraint for all 89 EDs") and S5 in §5.5 ("≥1,010,000 neutral 91-seat maps"). All 1,010,000 plans have 87 districts, the 2019 map's count, and the ±25% band applies around a quota of 2021 population / 87 (48,995). The 89-district shapefiles only score the two commission maps. Those passages now say so. S5 and §8.1 item 2 now treat the 87-district comparison as a cross-size headline, with the size-matched sets of Amendment 5, Parts 14–17 beside it. The Executive summary, the Abstract and the §5.4.9 Mahalanobis paragraph now say the joint p compares 89-district maps with 87-district plans, and that a size-matched joint test is pending. No percentile changed. The same district count was corrected in `analysis/methodology/methodolog` `analysis/methodology/plain_lang` and `preregistration/thresholds.md` §B.2.1.D (Amendment 5, Part 19). Primary: `n_districts` in `data/simulation_checkpoints_can`

C19 — 2026-10-30 THE CROSS-SIZE DECLINATION CAVEAT HAD THE SIZES REVERSED.

The §5.4.10 caveat said the 2019 map was the cross-size case, scored against an ensemble of 89-district plans, and that the 2026 maps and the ensemble were all at 89. The plans have 87 districts, so the 2019 map is the same-size comparison and both 2026 maps are cross-size. The ln(87)/ln(89) = 0.9949 bound still holds. Rescaling the 2026 maps' declination by ln(89)/ln(87) moves the majority from p21.85 to p21.74 and the minority from p98.79 to p98.81.

The caveat now also says the bound covers declination only, not seats@50/50 or population MedAD. Primary: the chain CSVs above; `data/outputs/simulation_real_ma`

C20 — 2026-10-30 THE SHORT BURSTS DID NOT START FROM THE 2019 MAP.

The §5.4.3 short-burst analysis said its 500 chains ran "from the 2019 enacted baseline" to map "the reachable neighbourhood of the 2019 map". It read the result as "a directed departure from the 2019 baseline", and placed the 2019 map "at the edge of the random-walk space around it". The 2019 map breaks ±25% on 2021 population (7 of its 87 districts), so every chain started from one fresh 87-part `recursive_tree_part` seed, and the 2019 map supplied only the district count. The canonical chains start the same way. The finding now says the 2026 maps lie outside what short random redistricting from a neutral start produces. The burst percentiles did not change. The §5.4.9 substrate note, `findings/simulation_short_burst` `analysis/methodology/mcmc_ensem` and the plot title in `analysis/scripts/mcmc_ensemble.` were corrected to match. Primary: `run_ensemble` in `analysis/scripts/mcmc_ensemble.` `analysis/scripts/simulation_sho` `data/va_pop_from_das.csv`.

C21 — 2026-10-30 WHY THE 2019 MAP HAS NO MEDAD OR REOCK PLACEMENT.

The §5.4.9 table note said 2019 was not scored on population MAD or Reock because it is an "87-seat map, different quota denominator". The plans have the same 87 districts, so size is not the reason. On 2021 population, 7 of the 2019 map's 87 districts fall outside ±25%, so the map lies outside the space the ensemble samples. Scored anyway, its MedAD is 3,085 (6.3% of quota), at p41.1. The note now says this and marks the 2026 MedAD and Reock rows as cross-size. Primary: `data/va_pop_from_das.csv` on `data/shapefiles/derived/va_poly`

grouped by `parent_ed_2019`; `population_mad` in the chain CSVs.

C22 — 2026-10-30 THE SEATS@50/50 CEILING COMPARED TWO LATTICES.

§5.4.8 said the DPG-era ceiling figures "survive on the canonical substrate". §4.3.1 row 3, §5.4.9, §6.2.5 and §6.2.8 gave "~69" or "<100" of the 1,010,000 plans as reaching or exceeding the minority's value, and §5.4.10 said the minority went "beyond the ensemble's upper bound". The 87-district plans can only take values k/87. The minority's 46 of 89 (51.69%) sits just below their maximum, 45 of 87 (51.72%). The 69 plans at that maximum all exceed the minority. The hill-climb's best map has 46 of 87 (52.87%), on a different denominator from the minority's 46 of 89. The text now says 69 plans exceed the minority's value, all at 45/87, and gives each seat count with its own denominator. The minority's p99.99 is unchanged. The C15 statement that the "fewer than 100 … reach this" wording was unchanged no longer holds. Primary: `seats_at_50_50` in the chain CSVs; `data/targeted_burst_best.json`.

C23 — 2026-10-30 THE 2019 SEATS@50/50 PERCENTILE IS A TIE ARTEFACT.

§5.4.10 read the 2019 map's seats@50/50 placement of p78.54 as a "mild UCP tail", and said the majority left seats@50/50 "nearly unchanged (p78.54 → p78.54)". The plans take values k/87. The 2019 map's 40 of 87 differs from the plans' 40 of 87 only in the last floating-point digit, so the registered `pct_rank`, which counts ties by exact equality, ranks all 266,278 plans at 40 of 87 below it. Counted as ties, the 2019 map sits at p65.36. The §5.4.9 table and §5.4.10 now give the registered p78.54 with p65.36 beside it. The majority's 41 of 89 falls between 40 of 87 and 41 of 87, so its p78.54 is the share of plans with 40 or fewer UCP seats, the upper edge of the 40/87 block. On the 89-district constrained nulls of §5.4.1 the majority sits at p51 to p57. `pct_rank` itself is unchanged, because the scoring spec pins it.

Primary: the chain CSVs; `data/outputs/constraint_enforci`
`data/outputs/constraint_enforci`

C24 — 2026-10-30 THE CONSTRAINT-ENFORCING RUN WAS COMPLETED.

The §5.4.9 constraint note said a constraint-enforcing re-run "is listed as future work in H6 but was not completed before submission". That contradicted §5.4.1. A run that holds the s.15(2) districts at the commission boundaries was completed on 2026-06-13, at 100,000 steps for each of two seeds, and every plan in it has 89 districts. The minority's mean-median, declination and seats@50/50 tails hold there, at p98.7 or higher, and at p98.3 or higher once the 1,000,000-step runs for both seeds are included (lowest: minority-seeded declination, p98.35). The note now says so, and the §5.4.1 line that called the larger run "queued" now reports it. A new §5.4.9 paragraph describes the size-matched sets of Amendment 5, Parts 14–17. A result from those sets is final only when its pooled n_eff reaches 400, and none has reported yet. Primary: `findings/constraint_enforcing_e` the two `constraint_enforcing_100k_*summ` and two `constraint_enforcing_1000k_*sum` files; `findings/pre_registration_amend`

C25 — 2026-10-30 THE ENSEMBLE POPULATION FLAG HOLDS ONLY UNDER THE ±12.5% PROPOSAL BAND.

"Population MAD" named two statistics. The 48% headline in §5.1.1 (3,180 against 4,707) is the mean absolute deviation from the 54,929 average, on the commission's July 2024 tables. The ensemble channel in §5.4.9 (2,827 against 3,938) is the median absolute deviation from the median district, on 2021 census population; it is now called MedAD. §5.4.9 said the minority's p99.1 "confirms the Lane-1 partisan signals are accompanied by unusual population-distribution asymmetry" and "adds a fifth flag". That placement holds only under the canonical ±12.5% proposal band. Under the ±25% statute band

the minority sits at p0.013 (135 of 1,010,000 plans are more equal) and the majority at p0.0, so both maps are more equal than almost every neutral plan. The flag is now stated as conditional on the proposal band until the statute-band set (set B, Amendment 5, Part 14) reports, in §4.3.1 row 8, §5.4.9, §5.5 and §6.2.3. The majority's MedAD percentile is given as p15.9 throughout (it was p15.8 in two places), and the data supplement's p99.0 and p15.8 are now p99.13 and p15.87. The public report no longer says the two measurements agree, and gives the 99th-percentile placement with its band. The same change was made in `findings/eps_full_robustness.md` `findings/joint_outlier_score_su` and the plain-language defense, which had defined the 3,180 / 4,707 figure as a median. Primary: the chain CSVs; `data/outputs/simulated_ensemble` `data/outputs/simulated_ensemble` `data/reference/majority_2026_po` `data/reference/minority_2026_po`

C26 — 2026-10-30 THE MEDAD PLACEMENTS ARE CROSS-SIZE.

The canonical-band MedAD placements compare 89-district maps with 87-district plans, and the plans' quota is larger (48,995 against 47,894). Measured as a share of each map's own quota, the placements are p21.0 (majority) and p99.6 (minority), against p15.87 and p99.13 in raw persons. The raw comparison understates the majority's placement by about 5 points and the minority's by under 1 point. The statute-band placements stay below p0.1. A cross-size note in §5.4.9 and the data supplement now says this. Primary: the chain CSVs; `data/outputs/simulated_ensemble` the 2021 population on the 4,765 voting areas (4,262,572), `data/va_pop_from_das.csv`.

C27 — 2026-10-30 THE "ACTUAL SEATS" ROW MIXED TWO SUBSTRATES.

The §5.2.1 row "Actual seats (NDP / UCP)" gave the real 2023 result (38 / 49) for 2019 and election-day-substrate counts for the 2026 maps (34 / 55 and 29 / 60). On the same substrate the 2019 map gives

30 / 57, so the row overstated the UCP gain under both 2026 maps. The row is now "Seats on 2023 election-day votes (UCP 57.4%)": 30 / 57, 34 / 55 and 29 / 60. Two rows follow it: seats at the actual 2023 two-party share (UCP 54.4%, uniform swing), 41 / 46, 45 / 44 and 36 / 53; and the actual 2023 result, 38 / 49. The same change was made in `findings/partisan_bias_summary.` Primary: `data/shapefiles/derived/va_poly` (`va_ndp`, `va_ucp`); `data/reference/alberta_2023_res` `data/outputs/simulation_real_ma`

C28 — 2026-10-30 B4 FOR THE 2019 MAP.

B4 took the 2019 value from the full statement of vote (46 NDP seats at 50/50) and the 2026 values from the election-day substrate. On the substrate the 2019 map gives 47 NDP / 40 UCP, so its asymmetry at 50/50 is 7, not 5. This changed in §5.2.1 and in the §6 summary table. The 2019 NDP share, standard EG and mean-median cells still use the statement of vote, and the §5.2.1 footnote now says which cells use which substrate. Primary: as C27.

C29 — 2026-10-30 ELECTION-DAY VOTERS WERE MORE UCP THAN THE ELECTORATE.

`analysis/methodology/methodolog` said the partisan metrics score "Actual Votes Cast". They score election-day votes. UCP took 57.4% of the election-day two-party vote (514,712 of 896,644), against 54.4% of all two-party votes (928,900 of 1,706,304). §3.2 item 5 now discloses this. It says seat counts on the substrate are not actual seats, that seats at 50/50 and the mean-median gap remove most of the shift, and that raw seat counts and the efficiency gap do not. Primary: as C27.

C30 — 2026-10-30 THE SIZE OF THE MAP EFFECT.

§5.2.6 called "a 1–3 seat shift from map design" a rounding error at the 2023 spread, and said the map effect matters only within "roughly five seats" of a tie. On the election-day substrate the two 2026 maps differ by 5 seats, both at that substrate's own vote level (UCP 55 against 60) and at a tied vote (NDP

48 against 43). Swung to the actual 2023 two-party level (UCP 54.4%), they differ by 9 (UCP 44 against 53). Against the 11-seat 2023 spread, that is not a rounding error. The text now speaks of a 5–9 seat effect. The plain-language defense's "1–3 seat" statements now give 5 seats (48 against 43). Primary: as C27.

C31 — 2026-10-30 THE "FULL-VOTE" SUBSTRATE IS NOT THE FULL VOTE.

The sensitivity substrate in §5.2.10 and §5.4.1 (T1.16) was called "full-vote", and §5.4.1 said its advance ballots were "apportioned to VAs by election-day two-party shares". It holds election-day votes plus apportioned advance, mobile and special ballots: 1.54M of the 1.71M two-party votes, with the 162,165 Vote Anywhere two-party votes left out. It is more UCP (55.3%) than the actual result (54.4%). Each poll group keeps its actual party split; election-day votes only set how a group's ballots spread over its voting areas. The substrate is now called "apportioned-ballot", with that description. H8 in §7.0 now says the same, and that its run predates the Vote Anywhere exclusion and placed all 1,706,304 two-party votes, at UCP 54.4%. No sensitivity value changed. Primary: `va_polygons_with_full_2023_vote` (`va_ndp_full`, `va_ucp_full`); `data/reference/alberta_2023_res` `data/outputs/advance_vote_sensi` [2026-11-05: the exclusion itself is corrected in C51.]

C32 — 2026-10-30 THE 2019 MAD IN THE DISCUSSION TABLE WAS A MEDIAN.

The §6 table gave the 2019 map's "Population MAD from avg" as 2,010, beside means for the 2026 maps. 2,010 is the median deviation. The mean on the 2017 report's populations is 2,886 (6.2% of a 46,803 quota), as Appendix C uses, and the table now gives it. §5.4.10 used the same 2,010 beside the 2026 MedADs and read the order "2019 < majority < minority" as showing the minority's deviation is larger than any predecessor's. Those figures are three statistics on three bases. The paragraph now gives each with its statistic and base and says they

should not be ranked. On one base, the 2021 census on voting areas, the mean deviations are 9.7% (2019 map), 10.1% (majority) and 10.2% (minority) of quota, and the MedADs are 6.3%, 5.9% and 8.2%. Primary: `data/reference/alberta_2019_pop` `data/reference/majority_2026_po` `data/reference/minority_2026_po` the voting-area overlay in C33.

C33 — 2026-10-30 APPENDIX C COMPARED FIGURES ON DIFFERENT BASES.

Appendix C set the 2019 map's mean deviation on the 2021 census (4,745) beside the 2026 maps' on the July 2024 tables (3,180 and 4,707). It concluded that the majority "improves on the benchmark" and that the minority reproduces the 2019 map's spread. It also said the 2026 maps could not be scored on the 2021 census because their shapefiles were unreleased; they arrived on 2026-05-06. Appendix C now scores all three maps on the 2021 census, summed over the 4,765 voting areas, each against its own quota: 2019 map 4,746 (9.7%), majority 4,847 (10.1%), minority 4,871 (10.2%). On that base the three are almost level, and the 48% gap in §5.1.1 shows only on the commission's tables. A new cycle-lag paragraph notes that growth since 2021 was uneven, from 0.9% below the 2021 count to 30.0% above it on 2019 boundaries. Item (iii) of the Author disclosure bias self-audit, §3.3, the §5.1.1 data-basis note and the plain-language defense now match. Primary: `data/va_pop_from_das.csv`; `data/shapefiles/derived/va_poly` `data/shapefiles/canonical/ea_ma` `ea_minority_2026_eds.gpkg`; `data/outputs/a1_legal_baseline_` `data/outputs/province_wide_drif`

C34 — 2026-10-30 THE PLAIN-LANGUAGE DEFENSE BROUGHT TO CURRENT VALUES.

`analysis/methodology/plain_lang` carried findings and figures from before the canonical run or later corrections. Corrected in place: (i) It said the majority is within the neutral band on every metric. It is within the null on three of four metrics and jointly (p = 0.102), and

its mean-median is a p0.99 outlier leaning NDP. (ii) Its §5.2.1 entries gave B3 −0.66 / −1.20 pp, B4 45 / 46 and EG p94.4. The Phase 4C values are −3.64 / +1.03 pp, 48 / 43 and p94.54. It now says 4.10% is the registered Option D line and the clean rerun's 95th percentile is 4.08%, and marks the blend-era −0.40% / −1.81% as superseded (C5). (iii) Its declination entry gave 2019 −0.034, majority −0.021 and minority −0.015, at p1.21 (NDP tail). Under the corrected sign (Amendment 5, Part 9) they are +0.045 (p91.33), −0.027 (p21.85) and +0.077 (p98.79, UCP tail), so declination agrees with the other three metrics. (iv) Its §5.2.9 entry gave v0_7 DPG values (minority responsiveness 1.41, majority 0.76). The canonical responsiveness is 2.87, 1.12 and 1.69 seats per 1% swing (2019 map, majority, minority). (v) R^ 1.007–1.017 is now 1.00011–1.00205, and "1,400–1,700" independent draws is now 1,413–1,522. The majority's mean-median is at p0.99, not p0.85. The minority's mean-median is beyond 99.97% of plans, about 335 per million, not 99.98% and about 200. The canonical seed's drand round is 5,500,000, not 5,800,000. The 2019 percentiles are p91.33 (declination), p91.81 (mean-median) and p78.54 (seats@50/50; p65.36 once ties are counted), not p91.05, p91.5 and p77.8. The retired Fisher p is about one in 22 million, not "once in 15 million". (vi) The count "over 1,140" submissions is removed. It did not match the ~1,340 in §5.9.4, and the archive is not in the repository to recount. Primary: `data/outputs/simulated_ensemble` `findings/joint_outlier_score.js` `findings/extended_partisan_metr` `findings/joint_empirical_bound_` `data/outputs/simulation_converg` `analysis/scripts/packing_cracki` `analysis/scripts/drand_seed.py`.

C35 — 2026-10-30 THE DATA SUPPLEMENT BROUGHT TO CURRENT VALUES.

(i) The §D6 R^ table gave the s58a6-B diagnostic (2026-05-10, 4 × 62,500 draws) under the full run's label, with efficiency gap and declination marginal against the Vehtari 1.01 line. It now gives the

full 1,010,000-plan run: GR92 R̂ 1.00011, 1.00205, 1.00016 and 1.00149, and pooled n_eff 1,522, 1,448, 1,513 and 1,413 (efficiency gap, mean-median, declination, seats@50/50). All four pass both lines; the rank-normalized split R̂ is below 1.01 for each. The 2026-05-10 file is listed separately with its own date and draw count. (ii) The retired Fisher paragraph paired T = 39.0 with the recomputed p ≈ 4.61×10⁻⁸. It now gives T = 39.87 with that p, and labels the table as the figures published on 2026-06-10. (iii) §D7 listed the Ch2 seed 23,687,475 under an s58a6 salt. It comes from drand round 5,500,000 with the salt `szat-bootstrap`. The s58a6 Section A row now points to its ten per-seed salts. Primary: `findings/joint_empirical_bound_` `data/outputs/simulation_converg` the chain CSVs; `findings/joint_outlier_score.js` `analysis/scripts/drand_seed.py`; `preregistration/seed_robustness`

C36 — 2026-10-30 THE 2019 MEAN-MEDIAN PERCENTILE IN §5.4.10.

The §5.4.10 table and its metric-by-metric reading gave the 2019 map's mean-median as p91.5. The canonical percentiles (`data/outputs/simulated_ensemble` and the §5.4.9 table give p91.81, as C34(v) records for the plain-language defense. Both places now read p91.81. The reading is unchanged: the 2019 map sits slightly on the UCP side of most neutral plans. Primary: the CSV above.

C37 — 2026-10-31 THE NOVEMBER COMMITTEE'S SIZE, AND THE MOTION AND DATE THAT CREATED IT.

The site's English copy called the Select Special Committee on Electoral Boundaries a committee of five MLAs, in places "three UCP, two NDP", six times. In six places it dated the Assembly's action to April 16, 2026, and in four it named a "Motion 19". Two lines also spoke of the committee's "five votes" (the opinion piece and the norms page); they now say "the votes" and "the MLAs' votes", since the chair's vote depends on the committee's rules. The evidence page's "three weeks

later" for the time from the commission's report to the takeover now says four. The Legislative Assembly's committee page lists six members, four UCP and two NDP, and says the committee "was established by Government Motion 37, passed by the Assembly on April 21, 2026"; CBC reported the 44–36 vote that afternoon. The motion was introduced on April 16. No source for a "Motion 19" was found, as flagged on 2026-10-29 (`proposals/site_rewrite_2026-10-29/legal_framework.md`, item 5). The copy now says six MLAs, four UCP and two NDP, created by Government Motion 37 on April 21, 2026. Sources: `evidence/legislature/assembly_c10-31.html` and `evidence/README.md`. No finding changes.

C38 — 2026-10-31 SITE ENGLISH COPY, CHECKED AFTER THE VOICE PASS.

The voice pass changed no fact; its writers listed what looked wrong (`proposals/voice_pass_2026-10-31_flags.md`), and each lead was checked against its source. Corrected in `viewer/src/lib/i18n/locales/en.` written submissions are 1,345 (198 before the interim report, 1,147 after; final report p. 14), not 1,147 or about 1,340 (9 places); Canada takes a census every five years, and the commission started from the 2021 census updated to a July 2024 provincial estimate; the north-east and central Calgary districts are about 8.5% larger on the minority map, not "a quarter larger" (11.5% against 2.8% above the provincial average; 3 places); the minority's efficiency-gap percentile is 94.5th (p94.54), not 94th (4 places), and the majority's is 16.5th, not 15th; the majority's tied-vote seat share is the 78th percentile, not the neutral median (2 places); Airdrie is not bigger than Red Deer (2021 census 74,100 against 100,844); voting area 043 is more than four-fifths the size of Prince Edward Island, not larger; the chair flagged four boundaries, three of them confirmed (3 places); the November section's committee is six MLAs, four UCP; the 1992

committee precedent is acknowledged where the copy called the takeover without precedent (3 places); the legal lessons number eight, not five; the efficiency gap is one of Act II's four fairness measures, not its headline; the minority crosses four of five structural tests, not every one; three litmus rows depend on votes, not two; the rural-count arithmetic is completed; the glossary gives the statutory "electoral division"; the commission's report has no automatic legal effect, unlike "some other jurisdictions" rather than "most provinces". No finding changes.

C39 — 2026-10-31 PUBLIC REPORT, CHECKED AFTER THE VOICE PASS.

In `reports/public/report_public.md` the census runs every five years, and the commission started from the 2021 census updated to a July 1, 2024 estimate (4,888,723); "a quarter larger" becomes about 8.5% larger, and the Casing 3 heading no longer says "a quarter"; "five legal reasons" becomes eight legal lessons; 94th becomes 94.5th (2 places); the efficiency gap is one of Act II's four fairness measures, not its headline; Appendix B states the park-extension charge as the chair's, followed by the audit's check that the district qualifies without it; the DNA analogy now says the 90% is the chance someone else is the source; the subtitle says "Boundaries"; the footnote says six rationales remain, not seven; "most provinces" becomes "some provinces"; the Act places no limits, not "almost no limits", on what the Assembly does. No finding changes.

C40 — 2026-10-31 EXPLAINERS AND NORMS PAGES, CHECKED AFTER THE VOICE PASS.

The norms scorecard's tally row now matches its cells (1 Yes, 1 Partial, 5 No, 2 Pending), and its text refers to "No and Pending cells"; the explainers give 69 of 1,010,000 neutral maps scoring higher (canonical percentiles; C22), not 66 matches; 94th becomes

94.5th; the DNA analogy is corrected as in C39; "most provinces" becomes "some jurisdictions"; the Act places "no constraints" on the Assembly; the Act was amended, not rewritten, in 1995; the norms page's submissions are 1,345, not 1,147 (2 places). No finding changes.

C41 — 2026-10-31 README AND FINDINGS BRIEF, CHECKED AFTER THE VOICE PASS.

README: the dependency graph is 279 nodes and 410 edges (`audit_dependency_graph.json`), in all three places, and "zero orphan findings" is cut (the same file lists six); Ch2 is p = 0.0024 (C8) throughout; Version A is p = 0.0348 on the canonical run (the two labelled round-1 mentions of 0.0303 stay); the pre-registration paragraph now says which predictions came before their results, as the record does; the sixth table row's direction holds under all three attribution methods (C11); the withdrawn "14.5% processed" submissions claim becomes 1,252 of about 1,340 parsed. Brief: the Calgary zone is north-east and central, and leans NDP, so the pattern packs NDP votes (heading corrected); the lanes list their findings correctly; 60 seats unlock no special power in Alberta; Cochrane is about 21 km from Nolan Hill, not 75 km; "gerrymander" is no longer defined as unconstitutional (*Rucho*). No finding changes.

C42 — 2026-10-31 PLAIN-LANGUAGE DEFENSE, CHECKED AFTER THE VOICE PASS.

In `analysis/methodology/plain_lang` on the official 2019 files the asymmetry does not reverse (canonical 2019 run, §5.2.8: efficiency gap majority −1.32%, minority −0.49%; the minority stays the more UCP-favourable), so eight passages that claimed a reversal now say so; the "+0.75 / −0.51" figures came from the retired blend model; the sign convention is positive = UCP advantage (C13), corrected in three entries; the minority's tied-vote seat share is 51.69% UCP (46 of 89),

the p99.99 value, not 48.3%; 44.8% is the UCP's share in the typical neutral map; the commission used the 2021 census updated to July 2024 estimates (s.12(5)), and the 2026 census is not a decennial census; drand is run by the League of Entropy; the stricter spatial version of the boundary-choice test gives p ≈ 0.19; p = 0.102 means about 90% of neutral maps are less extreme; Airdrie is too big for one district; Government Motion 37 set both maps aside; the run was 1,010,000 steps; submissions are about 1,345; the retired 90% Monte Carlo figure is marked retired; §7 discloses that the area-weighted attribution gives +2.52 pp, an artifact (`findings/maup_attribution_canor`

The Author Disclosure section was not edited and still says the asymmetry reverses under 2019 votes; that wording, the §6.2.6 falsifier and the matching passages in this report are open. No registered finding changes.

C43 — 2026-10-31 SECOND ROUND: PROBLEMS FOUND WHILE CHECKING.

In the site copy, the public report, the README and the methods and law pages: voting area 043 is more than four-fifths the size of Prince Edward Island, not larger (report); s.13 of the Act now sets 91 divisions ("2026 c7 s2"), so the law section no longer calls the 91-seat bill unconfirmed; the methods page lists four honesty points, not three, names the League of Entropy as drand's operator, and gives the declination figure as about 98.8% (98.788%); the chair flagged four boundaries, three confirmed by the audit (report table and methods page); s.15(2) is described as any three of five criteria, of which a reserve or Métis settlement is one; the "no public support" statements are the majority's, written as "we", on pp. 59 and 62 of the final report, not the chair's in Appendix C (which lists hybrid districts), and they name five places (Airdrie, Cochrane, Chestermere, Red Deer, St. Albert), so the audit's tally against them is right on three, wrong on one (Chestermere) and partly wrong on one (Red Deer),

where the site had said right on three of seven and wrong on three; the README describes section 12 as the population-data rule and the amendment proposal only as it is written; the report's Casing 14 and Appendix N now match the site on the Nova Scotia (2017) and *Lalande* (2026) decisions; "the largest city without its own MLA" is cut, because on all three maps Airdrie has a district mostly its own. No registered finding changes.

C44 — 2026-10-31 THE 2019 ASYMMETRY DOES NOT REVERSE ON THE OFFICIAL FILES.

Several passages said the minority–majority asymmetry reverses under 2019 votes (§1.2 item 3 and synthesis, §4.5, §5.0.1 item 4 and its table row, §5.2.3, RT3 in §5.7, §6, §8, Appendix A.1). §1.2 item 3 also read its own "+0.83 pp" with the wrong sign: on its majority − minority convention the 2019 value is −0.83 pp, the same direction as 2023's −3.92 pp. The canonical 2019 run (Option C, §5.2.8; `data/simulated_ensemble_percent` gives efficiency gap majority −1.32%, minority −0.49% (positive = UCP advantage, C13), so the minority stays 0.83 pp more UCP-favourable. Mean-median (0.0175 vs 0.0252) and seats@50/50 (45 vs 48 of 89 UCP) point the same way. On the official files the minority is the more UCP-favourable map in all three elections (+2.96, +0.83, +3.92 pp). What 2019 votes change is the size and the placement: both maps' EGs turn negative because the whole 2019 ensemble does (median −1.25%), and the minority's EG sits at p70.4, inside the normal range, while its mean-median (p96.1) and seats@50/50 (p98.5) stay in the UCP tail. The "+0.75 / −0.51 / +0.03 pp" figures came from the retired blend model (`findings/cross_election_2015.m` superseded); they are kept where they appear, labelled as blend figures, and the blend-era mechanism in §3.3 is labelled as the blend's alone. RT3 now reads "fails on magnitude, passes on direction" (0.83 against 3.92 pp exceeds the pre-registered 50%

line, threshold #27). The one-seat flip in §5.2.3 ES-19 is the crosswalk probe's, between 2023 and April 2026 polling, not 2019. Separately, §5.4.2's "structural floor" called the neutral median's mean-median (−0.019) and seats@50/50 (0.448) UCP-favoured. Both lean NDP (1.3% of canonical plans have mean-median > 0; 0.19% give the UCP half the seats at a tied vote), and 90% of plans fall between 42.5% and 48.3%; only the efficiency gap leans UCP (85% of plans). §8.1's "any neutrally-drawn map" is now "most (85%)". The Author Disclosure still says the asymmetry reverses under 2019 votes, and §6.2.6 item 2, a pre-committed falsifier, rests on the same premise; both are left for the author. No registered finding changes.

C45 — 2026-10-31 AIRDRIE: ONE MINORITY DIVISION IS AIRDRIE-MAJORITY.

The site, the public report, the README, the findings brief, the plain-language defense, the explorer and this report said the minority map leaves Airdrie's residents a minority in every division it splits them into ("zero seats"; "each quarter"; "four representatives, none of whom has Airdrie as a primary constituency"), and that the majority concentrates 73.8 % of the city in one division. On 2021 census dissemination areas laid over Elections Alberta's official boundaries (`analysis/scripts/airdrie_split_` `data/outputs/airdrie_split_shar` `10-31.json`; district totals match the minority's Appendix E table), the minority's Airdrie-East is 89.6 % Airdrie and holds 54.7 % of the city; Calgary-Airdrie (24.0 % of the city) and Calgary-Foothills-Airdrie West (20.9 %) are Calgary-majority; Olds-Three Hills-Didsbury takes about 350 people, and only by area-sharing of cut census areas. The majority divides the city roughly in half between two Airdrie-majority divisions (Airdrie-East 49.4 %, Airdrie-West 50.6 %). By the audit's 2 % piece rule the split is three pieces to two (the town-split baseline as first signed on 2026-10-29 already read

"Airdrie 3/2"; Amendment 5, Part 17 keeps its total of 6); the majority report counts four (p. 62). Corrected throughout; the 73.8 % and 59.2 % figures, from pre-canonical geometry, are marked superseded in `findings/airdrie_highway_pretex` Open: the registered cracking-signature test (§5.3.2) records criterion C2 ("community is minority in each district") as a pass, which the official boundaries contradict for Airdrie-East; its result is held for the author's ruling and is unchanged here. The site's example that three of Airdrie's pieces tie rural land to urban-centred districts "in places where the majority doesn't" is cut: the majority's Airdrie-East attaches more rural and small-town residents (Rocky View County 6,103; Crossfield 3,599) than the minority's (4,692). Also open: the 0 % anchoring figure for Calgary-Foothills-Airdrie West awaits remeasurement on the official boundaries.

C46 — 2026-10-31 FIGURES, ALT TEXT AND CAPTIONS.

Lane 1 histogram. It said the minority is more UCP-tilted than "95%" of neutral maps; it is 94.5% (p94.54). It labelled the p95 line a "gerrymander threshold"; it is the audit's pre-set outlier line. Its caption said the shaded tail is the top 10%; it is the top 5%. It said neutral maps cluster near zero; nine in ten fall between about −1% and +4%. Its alt text placed the minority in the shaded tail; it sits just short of it. **Structural bars.** The chair panel counted the three boundaries the audit confirmed under a title that said the chair flagged three; he flagged four (C38, C43). The structural table's chair cell now reads 4 (3 confirmed). The Airdrie panel now notes that one of the minority's four districts holds about 350 people. **Airdrie schematic.** It drew the minority's four districts as equal quarters and is redrawn to scale from `data/outputs/airdrie_split_shar 10-31.json` (C45). **Captions.** They called the audit's ~4.1% line "the Alberta threshold line". **Explorer.** Its line note credited "the committee" with the maps' lines.

Figures regenerated from `analysis/scripts/article_figure` and `generate_article_figures.py`. The stale `report_public.pdf` (superseded in July by the markdown report, and carrying since-corrected errors) and the unlinked explorer prototype page under `spike/` are removed; both stay in git history. The public report's four figures now resolve on GitHub. No finding changes.

C47 — 2026-10-31 ERRATA APPLIED (NOW AMENDMENT 5, PARTS 22, 25 AND 28); THREE PASSAGES LEFT FROM THE 2019 CHECK.

The erratum signed 2026-10-31 20:15 MDT (now Amendment 5, Part 22) corrects the direction of retraction condition 4.3 B. §6.2.6 item 1 read a successful Issue #14 counter-map as the falsifier. The inference runs the other way. A constraint-legal map that meets the minority's stated community-of-interest rationales with majority-comparable anchoring strengthens the rationale-failure finding, because it shows the minority's low anchoring was not required by its stated reasons. The finding is weakened, or retracted if the evidence is decisive, by a demonstration that no such map exists. The test is unchanged. The plain-language defense's §6.2.6 entry, the site's and public report's retraction condition 1 and `analysis/methodology/retraction` are corrected the same way. Item 2's premise, "The 2019 cross-election direction reversal extends to 338Canada April 2026 polling", is struck: on the official files there is no 2019 reversal (C44). Its polling test stands as written. The defense's §5.9.1 entry repeated the process scorecard's claim that the Chief Justice of Alberta names the commission's chair ("EBCA §3–5"). Under s.2(1)(a) the Lieutenant Governor in Council appoints the chair, and the final report says Justice Dallas K. Miller was appointed that way (p. 13). Three passages left over from the 2019 check are also corrected. First, §5.2.8 explained the 2015 ensemble's UCP-favoured efficiency gap (median +8.10 %) by

the real 2015 result, in which the PC and Wildrose won most of the votes but few seats. That result would make the gap NDP-favoured. The run merges the PC and Wildrose votes into one UCP-equivalent (56.0 % of the two-party vote), and that party wins about 70 % of the seats on any map (61 of 87 in the median neutral plan; 63 and 65 of 89 on the majority and minority maps), so the NDP wastes far more votes. Second, §3.2's Rule C note read +7.41 % and +4.16 % as NDP-favourable. Under C13 they are UCP-favourable. The mechanism now matches the computed sign: the trailing-party rule hands narrowly won NDP seats to the UCP (NDP seats fall from 38 to 32 on the minority map and from 38 to 35 on the majority), and every NDP vote in those seats becomes a wasted vote. The note now says the probe ran on the retired blend model: its Rule A values are C5's −0.40 % and −1.81 % (`data/outputs/third_party_sensit`) Third, §5.2.2's sensitivity table holds 2023 votes, as cast in the 2019-map districts, not 2019 votes. No registered finding changes.

C48 — 2026-10-31 THE CRACKING-SIGNATURE TEST, RESCORED ON THE OFFICIAL BOUNDARIES: AIRDRIE NOT DETECTED; COCHRANE NOT CRACKING-ADJACENT; CALGARY-FOOTHILLS-AIRDRIE WEST'S CITY-LIMIT ANCHORING IS 10.8 %, NOT 0 %.

The registered rule (v1.2 audit prompt, commit 249cff7d; C3 threshold `preregistration/thresholds.md` row 12) detects a cracking signature only when C1, C2 and C3 all hold, and C2 requires the community to be a minority in each district it is split into. §5.3.2 recorded Airdrie under the minority map as "Detected", with C2 a pass. C45 established that the minority's Airdrie-East is 89.6 % Airdrie. Rescored with the rule unchanged (`analysis/scripts/cracking_signa` `data/outputs/cracking_signature` `10-31.json`, C45's method): C1 holds (four districts by territory, three holding at least 2 % of the

city, against a minimum of two); C2 fails in Airdrie-East; C3 fails as registered (74,100 in 2021 exceeds the 68,661 single-district ceiling, as do the 2024 and 2025 municipal counts) and passes only under the 2026-06-12 restatement that reads it as a two-district test, a reading that follows the gloss in `thresholds.md` B.3.3 but was never filed as an amendment. Under either reading the result is not detected, and the rule's "forced by population" outcome, which needs C1 and C2, does not apply. Cochrane, reported as a cracking-adjacent pattern with C1 and C2 passing, fails all three criteria: Calgary-Nolan Hill-Cochrane holds 99.9 % of its residents (no split) and is 65.9 % Cochrane. The majority map's results stand (not detected for Airdrie, Cochrane and Chestermere). The headline count becomes one formal signature (packing) plus one under reformulated E2 Reading B. Separately, the 0 % city-limit anchoring reported for Calgary-Foothills-Airdrie West came from pre-canonical geometry; the same measurement on the official boundaries (`analysis/scripts/airdrie_city_l` `data/outputs/airdrie_city_limit` `10-31.csv`) gives 10.8 % (5.9 of 54.7 km; 4.15 km within 20 m of the limit), and Calgary-Airdrie's free-drawn share is 9.4 %, not 70.9 %, so the highway-pretext reading in `findings/airdrie_highway_pretex` does not hold on the official boundaries. Airdrie split tables now give four districts by territory and three by people (≥ 2 %). Corrected in §1.1, §5.2.5, §5.3.2–§5.3.4, §5.5, §5.6, the site, the explorer pins, the public report, the README, the findings brief, the methods page, the plain-language defense, `findings/airdrie_highway_pretex` and `findings/checklist_baseline_sco` Not changed, because registered: `preregistration/null_hypotheses` (L266, L283, L347) still lists the Airdrie cracking signature as Structural-Robust-Durable, and `preregistration/retraction_cond` §3.2 keeps its conditions; both are

to be read with this entry. This closes the two items C45 left open.

C49 — 2026-11-01 THIRD ROUND: THE SITE, PUBLIC REPORT, README AND FINDINGS BRIEF CHECKED AGAINST THE RECORD.

Who flagged. The four boundary objections, the "bad faith effort" phrase and the "no public support" claim are the majority's words, written as "we" (final report, pp. 10, 59, 62–63); the chair is one of the three commissioners who signed them. All four documents now say "the majority" in their rendered text (three unrendered strings in `en.ts` still said "chair flagged" on 2026-11-01; this report was corrected in C50). Recommendation 5, the 91-seat proposal and the addendum stay the chair's alone. The registered names that say "chair-flagged" are kept (Amendment 5, Parts 23 and 24). **"Blind" tests.** The README and the site said the geometry tests ran without knowing which boundaries had been named; §5.8.2 inspects the four named boundaries directly. The claim is cut. **C43's tally.** C43 put the majority "wrong on one (Chestermere)". §5.9.4.1 and `findings/submission_search_find` rate Chestermere "Partially refuted", as they rate Red Deer, so the claim held in three of the five places and was partly wrong in two. **Anchoring comparator.** No source for a "70–85% Canadian norm" or for the Quebec 78%, Ontario 82% and BC 71% figures was found in the repository or by a web search on 2026-11-01. The comparison is now the 2019 map's 75.1% on the same measure (`data/outputs/municipal_anchorir` The claim that the minority's departures from municipal lines cluster at the flagged boundaries is cut: scored district by district with the audit's own scorer, Rocky Mountain House–Banff Park is 82.2% anchored, above the minority's average. **OSF qsgy8.** Registered 2026-05-06, it pre-registers a Phase 2 comparison of the two commission maps and a first, prospective plan for the committee's 91-seat map (four tripwires, MO #1–#4, and a

bootstrap seed). The November tests the site describes are the later, fuller set in `preregistration/november_2026_s` dated in this repository, so the site now cites that file. `preregistration/seed_commitment` labels qsgy8 the MCMC-seed registration; its OSF text does not bear that out. **Committee votes of October 28.** Now cited to the committee transcript (`evidence/legislature/ceb_transc 10-28.pdf`, pp. CEB-72 and CEB-74), which records both 3–2 votes. **Seats and votes.** On the official boundaries and election-day votes, the minority map keeps the UCP at 45 seats down to about 49.2% of the two-party vote (the site said 49.7%), and on the majority map the UCP needs to win by about 9 points (the site said 4). **Advance votes.** 395,472 is the NDP's advance, mobile and special vote; with the UCP's it is 809,660 (§3.2 item 5; corrected in the policy paragraph of §3.2 and in the site, report and brief). Other items in this round (the ±25% band and the s.15(2) exception, the neutral-map calibration of the structural flags, the privacy policy's description of sharing and analytics) are recorded in the commits that made them. No registered test or threshold changes.

C50 — 2026-11-01 FOURTH ROUND: THE CORPUS CHECK. Six read-only checkers compared the site's English copy, the public report, the README, the findings brief, the plain-language defense, the registered documents and this report with the primary sources (the commission report, the Acts, Hansard, the October 28 committee transcript, the audit's own outputs and OSF). The author approved the fixes as proposed; each was rechecked against its source before it was applied. **Packing**. §5.3.1 recorded the packing signature as detected, with P2 (Zone A winning margins at least 15 pp above the provincial mean) a pass on "13 of the 17 Zone A districts NDP-won", citing `data/outputs/votes_2023_minorit` That file gives 9 of 17, with a mean margin 12.3 pp below the provincial mean; 13 of 17 is the

majority map's count in it. Rescored on the canonical Phase 4C attribution (`analysis/scripts/packing_signa` `data/outputs/packing_signature_` `11-01.json`), 8 of the minority's 17 Zone A districts are NDP-won. Their mean winning margin is 15.0 pp against a provincial mean of 27.6 pp: 12.6 pp below, where P2 needs 15 pp above. P2 fails, so the signature (P1 + P2 + P3) is not detected. P1 still holds (Zone A districts average 11.5% above the provincial mean, against 2.8% on the majority map); that is a population-equality finding. The test was always exploratory: its criteria were written in the same commit as its first run. The engineered-boundary signature's reformulated Reading B is withdrawn too, because the populated places it said the minority passed over (Caroline, Nordegg, Mountain View County, the MD of Bighorn, Sundre) are already in the minority's district (final report p. 352). No formal signature is detected on the official maps (packing fails its margin test; cracking and the engineered-boundary signature are not detected); this supersedes the count in C48. **Nominations.** The statement that the minority report is the work of the government's nominees now cites the Legislative Assembly of Alberta notice "Electoral Boundaries Commission to soon begin consultations" (March 28, 2025; https://www.assembly.ab.ca/about/ and-announcements/2025/03/28/electo boundaries-commission-to-soon-begin-consultations; archived at `evidence/legislature/assembly_n` `03-28.html`, SHA-256 64b9986d5b7ec9c99df1c22777300512 It lists Dr. Julian Martin and John D. Evans, KC as "Nominated by the President of Executive Council", and Greg Clark and Susan Samson as "Nominated by the Leader of His Majesty's Loyal Opposition". The minority report is Martin's and Evans's. **What else this round corrected** in the site's rendered English copy, the public report, the README, the findings brief, the plain-language defense and this

report, wherever each item appeared: (1) *Status*: past tense — the advisory panel drew the map and reported on October 22; on October 28 the committee voted 3–2 to end its review without observations; the report had to go to the Assembly by November 2; it is the panel's map, not the committee's. (2) *Registration*: nothing was on OSF before May 6, about six hours after the shapefiles arrived; the structural tests were written down April 24, after both maps were measured, and the 4-of-5 line April 25; seeds come from a beacon round public since October 2025, and only the git record dates the salts; the commission-map results are exploratory; qsgy8's failed predictions (H2, H3) and r3zm7's failed Prediction B are reported. (3) *Structural tests*: described as differences between the two commission maps, since the registered lane fires on 93.5–95.5% of neutral maps; the partisan simulation carries the evidence; "outlier", "vindicate" and "confirmatory" are dropped for them. (4) *Odds*: the 1-in-1.14-million figure is a parametric extrapolation past every sampled map, not a count; the sample alone supports p below about 6.9×10^{-4}; the near-copy chains, the 87-district plans and the ±12.5% proposal band are stated beside it. (5) *Who flagged*: the remaining passages that put the boundary objections, "bad faith" and "no public support" on the chair alone now say "the commission majority". (6) *Public support*: scored on the five places the majority named (three hold, two partly wrong); Rocky Mountain House–Banff Park and Olds–Three Hills–Didsbury are reported separately; the "25–60%" accusation is deleted. (7) *Schools*: public divisions differ, but one Catholic division serves both Red Deer and Sylvan Lake; the minority wrote that rural residents "go to school" in the city, not that the places share a division; with the Cochrane, ranching-gloss and St. Albert corrections, the rationale check now reads two of six failing on population arithmetic, not five of six (§5.9.6). (8) *Intent*: effect

language replaces "firewall", "surgical fortification", "designed to", "engineered" and a process set up "to promote" the minority map; the Author's View intent lines and the "invited to find that suggestive" line are cut, as is this report's "where intent may suggest itself" paragraph; the defense leaves any defamation defence to counsel; the main page's expert-review banner is no longer shown. (9) *Anchoring:* the unsourced "70–85% norm" gives way to "close to the 2019 map's 75.1%". (10) *Recommendation 5:* it proposed the all-party select committee itself (p. 66); the majority said more seats would have helped (pp. 58, 65); the chair's "my colleagues do not agree" covers a narrower point. (11) *Lesser Slave Lake:* 30,011 people, not 27,079; the unanimous interim plan merged it with Peace River, not Athabasca-Barrhead-Westlock; both final maps protect it. (12) *Dates and sources:* the federal comparator is context, not a benchmark (Airdrie, Red Deer and Lethbridge each sit within one federal riding at about twice the provincial quota); Pal and Choudhry (2014) and the *Vavilov* anachronism are corrected; "ESRI and Google basemaps" is Elections Alberta's description of the whole commission, not the minority's words; the 2015 efficiency gaps exceed 7% on both maps; Enoch Cree Nation is about 10–15 km from Devon, not 50; Quebec 2010–11 is restated. (13) *Privacy:* the policy describes the feedback form's optional name and email. (14) *Registered documents:* their errata are filed as Amendment 5, Parts 29–39. Ledger entries C5, C8, C12, C15, C47 and C49 were corrected where this round showed them wrong. Two items are left to their owners: `data/outputs/minority_rationale` truncates R17, and Best et al. (2018) still needs its citation checked. No registered test or threshold changes.

C51 — 2026-11-05 THE VOTE ANYWHERE EXCLUSION WAS NOT NEEDED, AND ONE SENSITIVITY READING DOES NOT SURVIVE IT.

Who flagged. The seat-claim test of 2026-11-04 (`findings/seat_claim_test_result` re-added the apportioned-ballot substrate inside the 2019 districts and came up 74,398 UCP and 87,767 NDP votes short of the official result; the shortfall is exactly the 87 "Vote Anywhere (Out of ED)" rows that `advance_vote_splat.py` drops in its step C5 (2026-05-10) as "unattributable". **What was wrong.** The step treated those ballots as tied to the station where they were cast. Elections Alberta reports each row under the voter's own 2019 district, for that district's candidates, so the district is known; only the voting area within it is not, which is true of every other advance ballot the script already spreads by election-day share. **Fix.** `analysis/scripts/vote_anywhere_` spreads them the same way and writes `data/shapefiles/derived/va_poly` which equals the official UCP, NDP and other totals in all 87 districts (the script fails otherwise). The apportioned-ballot file is unchanged. The sensitivity scripts take `ALL_BALLOTS=1` and write `_all_ballots` outputs beside the old ones. **What changed.** (1) §5.4.1, T1.16: on all ballots the minority's EG is +2.55% (apportioned-ballot +5.79%, election-day +4.02%) and its declination +0.046; the majority's EG is −2.70%. **The statement that the minority's EG "would be flagged on the EG axis" on a fuller substrate is withdrawn as a failed finding**; it is kept in place with a note. The minority stays above the majority on all four metrics; the EG gap between them is +5.25 points (apportioned-ballot +5.27, election-day +3.92). (2) §5.2.10 SZAT sensitivity: score +0.0525, p = 0.0005 (was +0.053, p < 0.0001); the SZAT stays retired. (3) H8 ("REJECTED — inter-map invariant") **is withdrawn as a failed finding**; it is kept in place with a note. Its +1.12-point shift on both maps came from the v0_9 maps with every ballot placed. On the canonical maps with every ballot placed, the maps do not move together. Gaps between minority and majority, election-day → all

ballots: EG 3.92 → 5.25 points, seats at 50/50 5.62 → 4.49, mean-median 4.66 → 3.59, declination 0.104 → 0.138. Every gap keeps its sign; none keeps its size. The canonical apportioned-ballot run already showed this (seats at 50/50 gap 3.37), which the §5.4.1 note of 2026-06-12 called an overclaim of invariance without changing H8. (4) `advance_vote_sensitivity.py` had failed since the switch to canonical maps (it looked for a `name_2026` column); fixed, and its canonical output written to `data/outputs/advance_vote_sensi` so that the v0_9 output H8 cites is kept. (5) `szat.py` saved its permutation samples to one file for every configuration, so any sensitivity run overwrote the registered run's `data/szat_bootstrap_eg_samples.` the all-ballots run did, the registered file was restored from git, and the samples file is now named by configuration. (6) The November scoring spec (§4.2) commits to re-publishing within 14 days "if an attribution refinement (e.g., a corrected Vote-Anywhere or Phase 4F population validation step) shifts any flagged metric by more than the threshold margin." It does not fire: that clause covers the November map's flagged metrics, which Step C scores on election-day votes only, and this correction changes no election-day value. `preregistration/retraction_cond` names no advance-ballot or substrate condition. `findings/chen_rodden_decomposit` also read a Vote-Anywhere-excluding substrate; it was superseded on 2026-06-10 and is not rerun. **What did not change.** Every registered test, the canonical ensemble and the headline use election-day votes only and are untouched. The percentile columns in the sensitivity outputs rank a fuller-substrate value against the election-day ensemble and are reported by the script, not read here. Primary: `findings/seat_claim_test_result` `data/outputs/attribution_sensit`

`data/outputs/advance_vote_sensi`
`findings/szat_summary_all_ballo`

C51 ADDENDUM — 2026-11-05, MATCHED RANKING.

The withdrawal above compared an all-ballots level (+2.55%) with lines calibrated on election-day votes, which crosses substrates the same way the claim it withdraws did. Both ensembles were then replayed with their original seeds on all ballots (`findings/allballots_ranking/RE/`) every plan's vote-independent columns equal the original run's, so only the votes changed. Ranked against plans scored on the same ballots, the minority's EG is **p98.82** (election-day p94.54; 11,903 of 1,010,000 plans at or above it, against 55,169), its declination p99.82 (p98.79), mean-median p98.73 (p99.97) and seats at 50/50 p99.90 (p99.99). The majority's EG is p26.48 (p16.52) and its mean-median p1.24 (p0.99). The reconstructed panel map (provisional and kept out of the headline: two calibrations failed, at 49.0% and 13.8% of voting areas misassigned against a 10% limit, and the third, run after Amendment 10 withdrew the registered one-further-attempt limit on 2026-11-04, passed as a reproducibility run on pages already seen; Amendments 7, 9 and 10) against set D: EG p48.02 (p47.87), mean-median p77.41 (p17.00), UCP seats 51 of 91, p42.85 (58, p42.68); no registered size-matched flag fires on either substrate. The withdrawal of the level-threshold claim stands; read with it, the minority's EG and declination rankings are stronger on matched all-ballots data, not weaker. These percentiles replace the `ptile_full` columns of `data/outputs/attribution_sensit` This is sensitivity analysis: every registered test and the headline remain on election-day votes and are unchanged. For the November map, Amendment 12 (2026-11-07) then moved every registered step that uses votes to all 2023 ballots and P1's line to +1.39%; it was written after these all-ballots results, including the minority map's, had been seen (§8).

8. Conclusion

Three questions opened the paper. The answers are now on the table.

First, do the two commission proposals diverge in measurable, reproducible ways? Yes. Across eight sub-sections of §5 — population equality, partisan bias, signature detection, MCMC ensemble placement, the pre-registered checklist, symmetry-of-test-selection, geographic coherence, and procedural record — the minority 2026 proposal shows wider distribution (on the commission's 2024 tables), a larger Calgary zone gap, more city splits and more flagged anomalies than the majority. No formal packing, cracking or engineered-boundary signature is detected on the official maps, and both proposals were set aside by the same procedural path. Except where noted (§5.7 RT1, the §5.9.6 sub-claims, the submission archive), every number is reproducible via `python3 analysis/<script>.py` against checked-in data anchored in `docs/FROZEN_MANIFEST.md`.

Second, do the divergences run systematically in one political direction? Yes, with explicit qualifications. Four of the five structural dimensions (anchoring does not separate the maps) point in the same direction without depending on vote data, though reading them as partisan needs vote data. The one vote-based partisan-bias dimension is directionally consistent under all three elections' votes on the official files and under April 2026 338Canada polling, bar a one-seat gap in the crosswalk probe that the audit traces to the crosswalk model. Under 2019 vote input it shrinks to 0.83 pp, and the minority's EG falls inside the normal range. The audit reports the contingency as a property of the finding rather than a defect: the boundary effect is sensitive to which electorate is asked, and the direction holds across three independent vote-attribution methods within the 2023-era voter distribution (§5.2.7) and across the 2019-to-2023 electoral shift, but its outlier status does not.

Third, can the April 16 pivot be evaluated against a pre-registered falsifiability framework? Partially. The November tests, which decide the verdict, were written down in `preregistration/november_2026_scoring_spec.md` in June 2026 (dated in this repository); qsgy8's tripwires are reported beside the verdict. The 17-test checklist registered on OSF (9wp5y, 2026-05-07, no embargo) was scored on the panel's map on 2026-11-09, after its registered 72-hour window had closed (grid and its §5 result: `findings/checklist_9wp5y_panel_map.md`). The advisory panel delivered its 91-seat map to the committee on October 22, 2026, and the committee tabled the panel's report on November 2. The tests were then amended on November 2–7 (Amendments 7–13, `findings/pre_registration_amendment_log.md`). Amendments 7–10 were written before any of the panel's geometry was scored; Amendments 11–13 were written after results had been seen, and 12 and 13 each say "Not blind". Amendment 12 moves every vote-using test to all 2023 ballots and P1's line from +4.10% to +1.39%; it was written after the all-ballots results, including the minority map's, had been seen. The same scripts producing §5 will be run against the panel's map on official shapefiles, under those amended rules; this paper went to press before that scoring.

Scope of the finding. The minority 2026 proposal shows a pattern of structural irregularities and rationale failures beyond what the majority exhibits; these compare the two maps with each other, not with neutral plans, since the structural lane fires on most neutral maps (§6.2.2). Its partisan-bias magnitudes are below the Stephanopoulos-McGhee 7% investigable-bias threshold (proposed in the academic literature; never judicially adopted) but above the noise floor of non-partisan redistricting variance as measured against the 1,010,000-plan canonical ReCom ensemble. The April 16 government action replaced the commission's process rather than amending its output — in the author's view, the most government-controlled response among the cases reviewed in §5.9.3. Whether these facts support a constitutional challenge under the *Saskatchewan Reference* [1991] effective-representation standard is for counsel and the courts to assess (Appendix F).

Next steps. Following the receipt of the official shapefiles on May 6, 2026, the audit successfully replaced all Derived Provisional Geometries (DPG) with canonical boundaries. On May 7, 2026, Elections Alberta's GIS team responded to the audit's technical methodology questions (personal communication, Elections Alberta GIS staff). Three specific points were clarified: (1) VA polygons for the 2026 proposed boundaries did not yet exist, because the government's Select Special Committee might redraw the boundaries before they take effect; the audit therefore spatially joins 2023 VA polygons to the 2026 ED boundaries, which is the audit's own inference, not something EA confirmed; (2) the population estimation methodology was described and the EA contact noted it was reasonable for the study's purposes, without being able to confirm whether the underlying population data could be shared; (3) EA uses the current Alberta OpenData municipal boundary dataset for boundary work, and for Communities of Interest the commission used ESRI and Google basemaps with members' knowledge from public hearings rather than a formal GIS protocol. The audit's anchoring uses Statistics Canada 2021 census subdivisions, a different source. The audit's remaining modelling approximations (election-day-only vote substrate; 2021 census-based population) reflect structural features of EA's published data, not gaps EA's internal data resolves. The advisory panel's 91-seat map is the held-out test closing the pre-registration residual (§5.5). In response to speculation about "dummymander" vulnerability, the November analysis will apply projected 10-year suburban population growth to the canonical MCMC ensemble and test whether projected growth widens or narrows the minority's asymmetry over the decennial cycle.

What stands in the evidentiary record. The audit's contribution is documenting two commission proposals diverge systematically on five measurable dimensions, the direction of divergence favours the governing party under the available vote inputs (one crosswalk probe excepted), and the process that set both proposals aside departs from comparator Canadian practice in specific ways. These facts are reproducible from public data using checked-in code. They do not prove intent, and they do not by themselves establish a constitutional violation. What they do provide is the evidentiary substrate on which such judgments — by counsel, by courts, by voters, and by future commissioners — can be constructed.

8.1 Postscript — the audit as framework for the held-out test

In policy terms, the verdicts in §5 and §6.2 are now substantially moot. In April 2026 (Government Motion 37, introduced April 16, passed April 21) the Legislative Assembly set both commission proposals aside and assigned the remaining work to a six-MLA committee (four UCP, two NDP) chaired by Brandon Lunty (UCP, Leduc-Beaumont) and the independent advisory panel it engaged. The maps this audit measured are no longer candidates to become law. Whatever Alberta uses for the 2027 election will come from the Assembly's decision on the panel's map, not from either commission proposal.

This does not make the work in §4–§7 unnecessary. The commission audit was a framework-building exercise. It produced — and calibrated against three real Alberta maps (the 2019 enacted baseline, the majority 2026 proposal, and the minority 2026 proposal, applied symmetrically to all three) — the artefacts the next audit will need:

1. The four Alberta-calibrated EG thresholds (§5.2.8), including the 4.10 % MCMC-derived line, registered as the 95th percentile of the 1,010,000-plan canonical ensemble on official EA shapefiles (the clean rerun's 95th percentile is 4.08 %; for the November map, Amendment 12 replaces it with +1.39 %, the same percentile on all 2023 ballots, written after the all-ballots results, including the minority map's, had been seen).
2. The 1,010,000-plan canonical constraint-bound ReCom ensemble on Alberta's 2019 substrate (§5.4). Its plans have 87 districts. Any 89- or 91-seat Alberta map can be percentile-placed against it for the four partisan-bias metrics, as a cross-size headline. The size-matched sets of Amendment 5, Parts 14–17 are reported beside it (§5.4.9).
3. The structural-irregularity scorecard (anchoring %, MAD, Calgary geographic-zone gap, Airdrie-class community-split count, majority-flagged anomaly count), with majority-comparable benchmarks documented for every test.
4. The rationale-check framework classifying a contested redraw symmetrically across maps (qualitative, not pre-registered; §5.9.6).
5. The DPG construction pipeline (§4.1.5–§4.1.6), now extended through stage v0_8 with the perfecter and the nested-polygon ownership-inversion refinement, and the alignment-proof toolkit, all of which will accept the panel's map without modification when its data is published.
6. The two-lane verdict structure (§6.2) distinguishing partisan-bias-magnitude readings from cumulative-structural-pattern readings, so the next audit can report both lanes honestly even if they disagree.

With the panel's 91-seat map due before the Assembly by November 2, 2026, this audit's apparatus will be re-pointed at the new map and re-run as fulsomely and as faithfully as it was for the commission proposals. The scoring spec (`preregistration/november_2026_scoring_spec.md`, amended November 2–7 by Amendments 7–13; §8) is the audit's commitment to the follow-through; the 17-test checklist registered on OSF (9wp5y; §5.5) was scored on the panel's map on 2026-11-09, after its registered 72-hour window had closed (grid and its §5 result:

`findings/checklist_9wp5y_panel_map.md`). The directional flag the §6.2 verdict places on the November map will be made with the same scripts, against the registered thresholds and vote substrate as amended, with the same restraint on intent.

Two contextual reminders for the November audit.

Alberta's natural geography usually gives conservative voters an edge on the efficiency gap. The province's NDP supporters concentrate in city cores; UCP supporters spread across suburbs and rural ridings winning by efficient margins. Most neutrally-drawn Alberta maps (85 % of the canonical plans) produce a UCP-favourable efficiency gap as a structural starting point. On mean-median and seats@50/50, though, the typical plan leans NDP. The Chen-Rodden decomposition in §5.2.5 quantifies how much of any given map's partisan-bias signal is geography-derived versus drawing-derived; a future map cannot escape the geography component, only manage the drawing component. The audit's job is to separate the two clearly enough so legitimate criticism cannot be brushed off as "you're complaining about geography."

There are many ways to gerrymander, and not all of them register on the partisan-bias-magnitude lane. The minority 2026 proposal shows why both lanes matter: it is over the 2.2 % EG line and, under 2015 votes, the historical-swing line, and just below 4.10 % under 2023 votes, with three of four partisan metrics past p95; it meets four of five structural tests. The audit will look at both lanes when it scores the panel's map. The structural lane alone fires on most neutral maps, so the partisan lane carries the test of departure from neutral. Sub-threshold on Lane 1 is necessary for a clean verdict, but not sufficient.

The standard the November audit will hold the panel's map to is the same standard this audit held the commission proposals to: skew toward neutrality wherever the constraint set permits, document the choices when the constraints force a departure, and be prepared to defend any departure from comparator Canadian practice with evidence stronger than aesthetic preference. Whether the new map meets the standard is a question this audit cannot pre-judge. It is a question the same scripts will answer publicly, on the same timeline, against the same evidence base — because the held-out test is the entire reason the framework was built.

Acknowledgments

The author thanks **Raymond Mok** (Geomatics Team Lead, Elections Alberta) for providing the official 2026 commission shapefiles in response to the author's research access request and for answering technical methodology questions regarding VA polygon availability, population data, and the commission's municipal boundary and communities-of-interest data sources (personal communication, 2026-05-06 and 2026-05-07). Acknowledgment of data provision and technical assistance does not imply Elections Alberta's endorsement of the audit's findings, methodology, or conclusions.

The author also thanks the volunteer reviewers at Mount Royal University who reviewed draft sections prior to publication. Their names are withheld at their request. Acknowledgment of review assistance does not imply institutional endorsement by Mount Royal University.

Appendix A — Reproducibility

A.1 Three-election direction-stability of minority-majority asymmetry

The minority map's partisan-bias asymmetry relative to the majority map holds its direction across three Alberta election cycles (2015, 2019, 2023): on the official files (Option

C, §5.2.8) the minority's EG exceeds the majority's by +2.96 pp (2015), +0.83 pp (2019) and +3.92 pp (2023). The table below gives the retired blend model's minority-majority efficiency-gap asymmetry (percentage points), kept as a record; it is not the canonical result:

ELECTION	MAJORITY EG	MINORITY EG	ASYMMETRY (MIN−MAJ)	INTERPRETATION
2015	+7.25%	+7.28%	+0.03 pp	Minority essentially equal to majority
2019	+0.16%	+0.90%	+0.75 pp	Minority more UCP-favorable than majority
2023	−0.85%	−1.36%	−0.51 pp	Minority less UCP-favorable than majority

Caveat. *In the blend model the 2015 and 2019 asymmetries have the opposite sign to 2023, a result explained in §5.2.3 and §3.3: the minority's hybrid districts (Springbank, Bearspaw, Cochrane) occupy the blend model's transition zone between urban and rural NDP performance. Under 2023 (a competitive urban cycle), these territories trend NDP, widening the minority's UCP advantage. Under 2019 and 2015 (cycles with shallower urban NDP penetration), they trend rural, narrowing it. That change of sign is a property of the blend model: on the official files the inter-map asymmetry direction is the same in all three elections. The table's interpretation column reads the blend numbers with positive = UCP (C13), while the blend-era text read them the other way (C5); on either reading the blend's sign changes between 2019 and 2023. Individual-map signs are not stable: on the official files both maps' EGs turn NDP-favourable under 2019 (majority −1.32 %, minority −0.49 %). Full method and derivation at* `findings/cross_election_2015.md` *(now superseded).*

All scripts run from repository root:

```
python3 analysis/scripts/packing_cracking_analysis.py # §5.2 symmetric three-m
python3 analysis/scripts/electoral_forensics_population.py # §5.1 with A2 robu
```

Each script prints a gate PASS/FAIL line. Numbers in §5.1 and §5.2 above must match the corresponding gate-passed output.

Reproducibility artifacts. A version-pinned environment manifest (`requirements.txt` at repo root) pins the Python packages it lists to exact versions, except `pypdf`, which has a floor; `scipy` comes in through `gerrychain` and is not pinned separately. An interpreter pin (`docs/setup.md`) names the tested Python version; `docs/FROZEN_MANIFEST.md` lists external URLs accessed during the audit with their access dates, though not yet every data-source URL in the References. A third party running the pipeline 12+ months from today can (a) install the pinned environment, (b) check each URL's state against the frozen snapshot, and (c) reproduce every numeric finding to the tolerance stated in Gate G0. Reproducibility-artifact provenance follows the ICLR 2022 Reproducibility Checklist and Nosek et al. (2018) Open Science Framework pre-registration standards.

Appendix B — Supporting Analysis Documents

- Section A
- Section C
- Section D
- Section 4

- Bias audit — self-audit of this audit's own methodology
- Design critique — hostile stress-test pass
- Methodological defenses — pre-emptive adversarial review: attacks on substrate, MCMC baseline, and partisan metrics with per-attack empirical responses
- Test apparatus defense — per-test criticism and response; addresses "are you making up metrics to have metrics?"
- Fisher combination defense — statistical rationale for combining Ch1 and Ch2 via Fisher's method (retired: the Fisher combination is no longer used)
- Fisher independence defense — argument the two channels are sufficiently independent for Fisher combination (retired)
- Warrington declination defense — declination metric applicability (its direction-disagreement with EG was a sign error and is retired; Amendment 5, Part 9)
- Urban weight defense — blend model urban-weight parameter justification
- Uncertainty analysis
- Academic literature review
- Submission search findings — §5.9.4 evidence base
- Chair's Recommendation 5 analysis — §5.9.2 evidence base
- Track C checklist baseline scoring — §5.5 full scorecard and comparison template for the November map
- MCMC ensemble baseline — §5.4 method, 10k-sample DPG-era ReCom chain (started from a neutral seed, not the 2019 map; C20), per-metric percentile tables
- Plan B compliance + contested-config cross-check — (standalone document not produced; see §3.3 disclosure)
- Cycle-lag analysis — province-wide ED drift under mid-2025 populations
- Proposed Act §12 amendment — legislative reform proposal addressing the census / cycle-lag tension
- Calgary data-sources audit — 16 Calgary-specific sources catalogued; ward-level modelled A2 sensitivity is feasible from public data
- Adversarial stress-test passes and their fortifications are not in the tracked tree. They are in the git history under `historical/` before commit `e4c32e89`.
- Chen-Rodden Alberta validation — mechanism-level test of the natural-packing argument
- Canadian redistribution base-rate catalogue — C4 partial catalogue (quantitative acquisition flagged as future work)
- Alberta government database survey — Track N, composite-basis source recommendations for §12 reform
- Commission source provenance audit — Track O, verified 4,888,723 matches StatsCan Q2 2024 postcensal estimate

- Byelection data and assessment — Track S, 2022–2025 byelections evaluated and not incorporated into RT3
- A1 legal-baseline computation — Appendix C companion; 2019-map MAD on 2021 Census directly
- Threshold provenance compendium — every numeric threshold justified with source + sensitivity
- Canadian inter-map base-rate computation — comparative distribution across seven Canadian redistribution cycles
- November 2026 scoring specification / platform analysis — pre-registration materials for the November signature-detection checklist

- CSD-level community splits — §5.8.4 robustness check
- 338Canada riding-level cross-validation — §5.2.3 independent cross-check
- Submission OCR log `historical/v0_1_submission_ocr_log.md`, in the git history before commit `e4c32e89` — §5.9.4 partial extension of the roughly 93 non-text-layer submissions

---

Appendix C — 2021-census legal-baseline A1 for the three maps

Purpose. §5.1.1 reports A1 MAD on the commission's own tables, which derive from the July 2024 OSI population estimate. A reviewer committed to strict §12(3) statutory-basis discipline can argue the §5.1.1 numbers inherit the commission's data-source status. This appendix computes A1 on the 2021 Census as the §12(3)-operative reference point. The official 2026 shapefiles arrived on 2026-05-06, so the 2026 maps are scored on the same 2021 base as the 2019 map.

Method. First, 2021 Census population at the dissemination-area level (6,203 Alberta DAs, `data/reference/alberta_2021_da_populations.csv`) aggregated to the 87 2019 EDs via geopandas overlay on `data/shapefiles/reference/alberta_2019_eds/EDS_ENACTED_BILL33_15DEC2017.shp`. Reproducible script at `analysis/scripts/a1_legal_baseline_2021_census.py`. Per-ED output at `data/outputs/a1_legal_baseline_2019eds_2021census.csv`. Second, for a like-for-like comparison of all three maps, the 2021 Census population on the 4,765 voting areas (`data/va_pop_from_das.csv`, the ensemble's population base) is summed by district. The 2019 map uses each voting area's 2019 parent division. The 2026 maps use the official Elections Alberta shapefiles (`data/shapefiles/canonical/ea_majority_2026_eds.gpkg`,

`ea_minority_2026_eds.gpkg`), with each voting area assigned by its representative point, as `score_exogenous_map` in `analysis/scripts/mcmc_ensemble.py` does. Each map's quota is the overlay total divided by its own number of districts. MAD is the mean absolute deviation from that quota.

Headline figures.

MAP & BASIS	DISTRICTS	QUOTA	MAD	MAD AS % OF QUOTA	SOURCE
2019 map, 2017-report populations (commission-quoted)	87	46,803	2,886	6.2%	EBC 2017 Final Report pp. 60–61
2026 majority map, July 2024 estimate	89	54,929	3,180	5.8%	Majority Report variance table
2026 minority map, July 2024 estimate	89	54,929	4,707	8.6%	Minority Report variance table
2019 map, 2021 Census, DA overlay	87	48,996	**4,745**	9.7%	`a1_legal_baseline_2021_census.py`
2019 map, 2021 Census, VA overlay	87	48,995	4,746	9.7%	VA overlay (Method, second step)
2026 majority map, 2021 Census, VA overlay	89	47,894	4,847	10.1%	VA overlay
2026 minority map, 2021 Census, VA overlay	89	47,894	4,871	10.2%	VA overlay

Ordinal comparison. *Only rows on the same base and the same quota rule can be ranked. On the commission's July 2024 tables, the majority is tighter than the minority (5.8% against 8.6% of quota). On the 2021 Census voting-area overlay, the three maps are almost level: 2019 map 9.7%, majority 10.1%, minority 10.2%. The 2019 map's 6.2% on its own 2017 base is not comparable with either set.*

Seven 2019 EDs outside ±25 % under 2021 Census. Central Peace-Notley (−44.77 %), Lesser Slave Lake (−44.73 %) — both s.15(2)-protected — plus Edmonton-South (+40.89 %), Edmonton-Ellerslie (+38.60 %), Edmonton-South West (+33.71 %), Airdrie-Cochrane (+29.76 %), Calgary-North East (+25.55 %). The five positive outliers are urban-growth EDs already exceeding the +25 % ceiling by 2021-census time; Track L's mid-2025 analysis (`findings/cycle_lag_analysis.md`) confirms all five remain out-of-band under 2025 populations.

Interpretation. The §5.1.1 gap between the two 2026 maps appears on the commission's July 2024 tables. On the 2021 Census it almost disappears: the minority's mean absolute deviation is 10.2% of quota against the majority's 10.1%. The 2019 map, at 9.7%, is slightly tighter than both on this base. This appendix therefore does not show that the majority improves on the 2019 map, or that the minority only matches it. A reviewer who accepts only the 2021 Census as the §12(3) base would find no meaningful mean-deviation gap between the 2026 maps. On the median-based statistic the minority stays wider on the same base (MedAD 8.2% of quota, against 5.9% for the majority and 6.3% for the 2019 map;

§5.4.10). The companion file `analysis/methodology/reference/legal_baseline.md` covers the 2019 map only.

Cycle lag. The commissions drew to the July 2024 estimate, not to the 2021 Census, and growth between the two was uneven. On 2019 boundaries, the audit's mid-2025 estimate ranges from 0.9% below the 2021 count (Fort McMurray-Wood Buffalo) to 30.0% above it (Airdrie-East), with Airdrie-Cochrane and Chestermere-Strathmore 23.3% above (`findings/cycle_lag_analysis.md`; `data/outputs/province_wide_drift_2019.csv`). A map drawn to equalise 2024 populations will look uneven on 2021 counts wherever growth was uneven. The 2021 rows therefore score each 2026 map on a base it was not drawn to, and the 2019 map on a base four years after the 2017 report it was drawn from. They say little about how evenly any of the three commissions drew.

Appendix D — Mathematical Formalism

D.1 Efficiency Gap (Stephanopoulos and McGhee 2015)

$$\text{EG} = \frac{W_A - W_B}{N}$$

```
EG = (W_A - W_B) / N
```

Wasted votes W_X for party X are defined as losing-district votes plus winning-district votes above the victory threshold, summed across districts; N_d and N are two-party (UCP + NDP) totals. The Phase 4C attribution (`packing_cracking_analysis.py`) sets the threshold at $\lfloor N_d/2 \rfloor + 1$; the ensemble scorer (`mcmc_ensemble.py`), which produces every ensemble EG and percentile, uses $N_d/2$. The two differ by at most one vote per district. The 7 % threshold is academic-literature authority only — never judicially adopted (see §5.2.8).

Sign-convention reconciliation. When party A is indexed first, Stephanopoulos-McGhee canonical EG uses a 2:1 slope baseline (positive EG = party A disadvantaged, i.e., party B has seat-advantage). This paper uses one convention throughout (§4.3): with A = NDP and B = UCP, positive EG means the NDP wastes more votes, which is a UCP advantage. (An earlier version of this paragraph described a 1:1-baseline reading in which negative EG tracked UCP advantage; that reasoning was retired by C13.) `analysis/methodology/sign_convention_resolution.md` carries a superseded banner.

D.2 Mean-Median Gap (McDonald and Best 2015)

$$\text{MM} = \bar{v} - \tilde{v}$$

```
MM = mean(v) - median(v)
```

$\bar{v}$ is the mean NDP vote share across districts; $\tilde{v}$ is the median. Positive MM indicates mean > median, consistent with party voters packed into fewer high-share

districts (cracking of the opposing party, or packing of own party).

D.3 Declination (Warrington 2018)

For an election with n total districts in which party R wins ℓ_R districts and party D wins ℓ_D districts ($\ell_R + \ell_D = n$), let $\bar{y}_R$ be the mean vote share for R across R's *won* districts and $\bar{y}_D$ the mean vote share for R across D's won districts. Define two angles measuring how far each party's mean winning share sits above the 50 % threshold, scaled by that party's seat fraction:

$$\theta_R = \mathrm{atan2}!\left(\bar{y}_R - 0.5,\; \tfrac{\ell_R}{2n}\right), \qquad \theta_D = \mathrm{atan2}!\left(0.5 - \bar{y}_D,\; \tfrac{\ell_D}{2n}\right)$$

($\bar{y}_D$ is below 0.5, so $0.5 - \bar{y}_D$ is D's mean winning margin above 50 %; θ_D is constructed so that a perfectly symmetric election produces $\theta_R = \theta_D$ and $\delta = 0$.)

Warrington's declination is $\delta = (2/\pi)(\theta_D - \theta_R)$. Positive δ indicates the party indexed as R is favoured by the seat geometry (R's wins clustered tightly near 50 % — efficient — while D's wins are clustered with wider margins — wasted votes); mathematically equivalent to packing of party D. (Note: earlier drafts of this Appendix wrote the formula as $(2/\pi)(\theta_R - \theta_D)$, which is *negated* relative to Warrington 2018 — that error was corrected 2026-06-12 as part of the sign correction recorded in Amendment 5, Part 9 of `findings/pre_registration_amendment_log.md`. The verification is below.)

Convention used throughout this audit (corrected 2026-06-12, recorded in Amendment 5, Part 9; consistent with `analysis/scripts/mcmc_ensemble.py:215`): R = UCP and D = NDP, so **positive δ = UCP-favourable boundary geometry (NDP packed); negative δ = NDP-favourable boundary geometry (UCP packed).** This is Warrington's original convention applied with R = the dominant party in the modelled election (UCP in 2023 Alberta). It is now the convention in every chain CSV, every real-map JSON, and every reported percentile in this audit; earlier (pre-correction) chain CSVs, JSONs, and percentiles carried the swapped-operand sign and have been migrated in place via `analysis/scripts/amendment_10_declination_migration.py`.

```
# Discrete computation (chain code reference: mcmc_ensemble.py:215 post-correc
# For each party, sort districts by UCP vote share.
# y_bar_ucp_in_ucp_won  = mean UCP share in UCP-won districts
# y_bar_ucp_in_ndp_won  = mean UCP share in NDP-won districts (= 1 - mean NDP
# l_R = # UCP-won districts; l_D = # NDP-won; n = l_R + l_D
theta_R = math.atan2(y_bar_ucp_in_ucp_won - 0.5, l_R / (2 * n))
theta_D = math.atan2(0.5 - y_bar_ucp_in_ndp_won, l_D / (2 * n))
declination = (2 / math.pi) * (theta_D - theta_R)  # Warrington 2018
```

Verification (T1.7 R1 Ref #5; reproduced T1.7 R2 Ref #5): a textbook 10-seat UCP gerrymander (8 seats at 55 % UCP, 2 seats at 20 % UCP) returns EG = +0.34 (UCP-favoured) and δ = +0.716 (UCP-favoured). Under the pre-correction (swapped-operand) formula the same

gerrymander returned δ = −0.716, contradicting both EG's direction *and* Warrington's NC-2014 published analog of +0.54 for the same geometry — the discrepancy that surfaced the bug.

Alberta results (canonical shapefiles, 2023 votes; corrected 2026-06-12, recorded in Amendment 5, Part 9):

MAP	Δ (CORRECTED)	PERCENTILE VS 1,010,000-PLAN CANONICAL ENSEMBLE
2019 enacted	**+0.045**	p91.33 (mild UCP-favoured side)
Majority 2026	**−0.027**	p21.85 (mild NDP-favoured side of median, within null)
Minority 2026	**+0.077**	p98.79 (UCP-favoured tail)

Under the corrected sign, all four partisan-bias metrics agree on the UCP-favoured direction for the minority map (EG +3.96 %, MM +1.04 %, δ +0.077, s50 0.5169). Three carry tail flags at ≥p95; EG is directionally aligned but sub-threshold (p94.54). The pre-correction "B6 disagrees by design" reading at earlier drafts of §5.2.4 was an artefact of the swapped operand, not a real cross-metric divergence; Warrington (2018) and Katz, King & Rosenblatt (2020) document EG↔δ tension on a non-trivial fraction of US-state maps, but the Alberta canonical minority on canonical substrate is not one of those cases once the sign is corrected. See §5.2.4 for the corrected reconciliation paragraph.

Substrate-iteration history (see also `findings/post_audit_recompute_deltas.md`). Under the swapped-operand convention used in earlier reports, the minority's canonical declination read −0.0666 (v0_8 DPG substrate) → +0.0105 (canonical first-pass, before the corrected Vote-Anywhere attribution landed) → −0.0770 (final canonical with corrected attribution). Under the Warrington-2018 convention restored by the sign correction (Amendment 5, Part 9), the equivalent values are **+0.0666 → −0.0105 → +0.0770**; the v0_8 and final canonical agree on UCP-favoured direction once corrected, and the transient first-pass +0.0105 (old)/−0.0105 (Warrington) reflected an attribution refinement (~9.4 % of votes) that has since been superseded. The earlier §6.2 reading of "p62.2, near median" derives from the transient first-pass value and is superseded by the final canonical **p98.79** reading.

D.4 Polsby-Popper compactness

$$\text{PP} = \frac{4\pi A}{P^2}$$

```
PP = 4 * pi * A / P^2
```

A = polygon area, P = perimeter. Range $[0, 1]$; 1 = circle. Values near 0 indicate elongated or convoluted boundaries. Gate threshold: mean PP < 0.15 (extremely fragmented). See Polsby & Popper (1991); Niemi et al. (1990).

Results (`v0_7` DPG historical, superseded; script `analysis/scripts/compactness_metrics.py`):

⚠ SUBSTRATE NOTE 2026-06-12 per T1.7 R2 Ref #10. *The table immediately below is the **v0_7 DPG historical** reading, preserved for trail-of-work. Canonical EA shapefile values supersede it (canonical*

*reading reported in the §5.6 / §6.2.2 / §5.8.4 narrative; the canonical Edmonton-Enoch-Devon PP is 0.534, not the 0.0652 minimum in the v0_7 historical table). The v0_7 minimum 0.0652 (Edmonton-Enoch-Devon) was superseded at §5.8.4 as a DPG transcription artefact; the canonical reading reverses the inter-map ordering (canonical: minority mean ≈ 0.432 vs majority mean ≈ 0.437; canonical EDs < 0.25: 6 minority vs 8 majority). The v0_7 table below is **historical only** and should not be cited for geometric-consequence claims; use the canonical numbers in §5.6 instead.*

MAP (V0_7 HISTORICAL)	N	MEAN PP	MEDIAN PP	STD DEV	MIN	MAX	EDS < 0.30	EDS < 0.40	GATE
2019 enacted	87	0.4186	0.3994	0.1189	0.1717	0.7691	16	44	PASS
Majority 2026	89	0.3564	0.3591	0.1375	0.0902	0.6910	29	60	PASS
Minority 2026	89	0.3344	0.3374	0.1470	0.0652	0.6994	39	63	PASS

The minority 2026 map appeared to have the lowest mean Polsby-Popper (0.334) under v0_7. Canonical recomputation reverses this finding: the minority mean is ≈ 0.432 vs majority ≈ 0.437; below-0.25 counts run 6 minority vs 8 majority (i.e., the majority has more elongated districts on canonical substrate). Full per-ED CSV at `findings/compactness_metrics.csv` (v0_7 historical); canonical values at `findings/polsby_popper_verdict.md`. All three maps pass the gate (mean PP > 0.15) under either substrate.

D.5 Reock compactness

$$\text{R} = \frac{A_d}{A_c}$$

```
R = A_district / A_smallest_enclosing_circle
```

Range $[0, 1]$. R < 0.30 flagged, the conventional threshold used in H10, C2 and `findings/reock_verdict.md`. Canonical per-district results are in `data/reock_per_district.csv` (`analysis/scripts/reock.py`); `findings/compactness_metrics.csv` holds Polsby-Popper only.

Appendix E — Geometric Data Provenance

The subsections below document the historical geometric-data paths evaluated in the first phases of this audit prior to the release of official shapefiles. § E.1–E.5 describe the initial attempts (direct-shapefile, DA-dissolve, VA-polygon-attribution, OSM reconstruction, and QGIS paths). § E.6 is the technical data statement. § E.7 reports the approximate-geometry analysis (Tier A/B compactness) produced as a substitute for the not-yet-released 2026 shapefiles. All provisional geometry findings were officially superseded on May 6, 2026,

when Elections Alberta provided the official canonical shapefiles. An additional "Note on population-data provenance and cycle-lag robustness" is preserved at the end of the appendix for completeness; its core findings are summarised in §3.3.

E.1 4A (direct shapefiles)

Resolved. Initially blocked on 2026-04-22 as 2026 proposal shapefiles were not published on the Elections Alberta maps portal. However, on May 6, 2026, Elections Alberta officially provided the 2026 shapefiles (`ea_majority_2026_eds.gpkg` and `ea_minority_2026_eds.gpkg`), triggering the sunset clause and transitioning the entire audit from Derived Provisional Geometries (DPG) directly to Canonical Geometry.

E.2 4B (DA dissolve)

Deprecated. This path would have attempted to reconstruct boundaries by dissolving 2021 Census DAs if the Commission's PDF report contained DAUID lists. It was formally deprecated on May 6, 2026, when the official shapefiles (E.1) provided the canonical boundaries directly, rendering DA-dissolve approximation obsolete.

E.3 4C (VA-polygon attribution)

Pipeline validated; full execution intentionally bypassed. Skeleton (`analysis/scripts/poll_attribution_skeleton.py`, now under `historical/` in the git history before commit `e4c32e89`) correctly parses the 2023 Statement of Vote: 1,973 poll records matched to four-figure official totals. The full execution (geocoding 1,973 polls directly into the 2026 shapefiles) would require ~4–8 hours of compute. This path was evaluated and intentionally bypassed because it does not yield a measurable precision gain.

Reasoning: 47.5% of 2023 two-party ballots were not cast on election day (advance, mobile and special ballots, including Vote Anywhere). Elections Alberta verified on May 7 — disaggregated VA-level mapping for these ballots does not exist. They are reported by division, so they can only be spread across a division's voting areas. The 87 "Vote Anywhere (Out of ED)" rows, about 9.5% of two-party ballots, are reported under each voter's own 2019 district and can be spread the same way (C51). Phase 4F (`va_attribution_area_weighted.py`) proved the residual geographic error on the Election Day straddle impacts exactly 1,396 votes (0.15% of the province) and shifts the minority map's `seats@50/50` metric by exactly +0.0000 pp. Placing every 2023 ballot this way changes the size of each minority–majority gap while keeping its sign (C51: on the efficiency gap it moves from 3.92 to 5.25 points), so the election-day substrate is not the limit of precision possible with public data. That gain comes from placing those ballots; geocoding the election-day polls, as the Phase 4F result shows, would add almost nothing.

E.4 4D/4E (OSM Reconstruction / QGIS Manual)

Deprecated. 4D (OSM feature-class snapping) and 4E (manual QGIS painting) were alternative paths to reconstruct the missing boundaries visually. Both were permanently deprecated on May 6, 2026, upon receipt of the canonical shapefiles, which provide exact vertices and eliminate the need for visual transcription.

E.5 4F validation

Superseded. Validation of the approximate geometries against Commission population targets was superseded by the canonical runs on the official shapefiles.

E.6 Technical Data Statement

- **Source data for §5.1 and §5.2:** CSV files in `data/` (populations for both 2026 maps; per-ED 2023 and 2019 vote totals); raw Statement of Vote in `data/raw/2023_results.xlsx`.
- **Source data for §5.8:** JPG map images from the commission's final report (all eight majority Appendix A panels; full coverage for minority).
- **Source data for §5.9:** Electoral Boundaries Commission Act, commission report via prompt context, comparator-case general knowledge.
- **Geometric reconstruction:** Superseded. The audit operates entirely on the canonical shapefiles.
- **Coordinate system / resolution / aggregation:** EPSG:3400 (NAD83 / Alberta 10-TM Forest) for the canonical shapefiles and voting-area polygons.
- **Integrity metric:** Population checksum (0.5% warn, 2% hard stop) does not pass on canonical shapes. On raw 2021 census counts against the commission's 2024 estimates, all 89 districts on each map fail the 2% hard stop; on the share-of-province comparison the audit reads, 78 of 89 majority and 72 of 89 minority districts fail, concentrated in fast-growth Calgary and Edmonton suburbs (§3.3; `findings/phase4f_hardstop_canonical.md`).
- **Geometric shift log:** None required. No manual geometric adjustments were applied to the canonical shapefiles.
- **Transformation log:** `compactness_metrics.py` and `reock.py` reproject to EPSG:3401 (Alberta 10-TM Resource), which differs from EPSG:3400 only in false easting, so areas and perimeters are unchanged.
- **Symmetry consistency:** B1–B4 use identical Phase 4C spatial attribution applied to both 2026 maps via the same `packing_cracking_analysis.py` v0.3 run (canonical EA shapefiles, exact VA-level centroid-in-polygon). The earlier 85/15 blending methodology is superseded by Phase 4C (§5.2.2). A1–A3 use identical variance computation against the same provincial average. A2 uses identical classification rule plus an alternative-rule robustness check (G4). Section C inspected all eight majority Appendix A panels; the remaining limit is that the anomaly questions were built from the minority's boundaries (§5.8.3).

E.7 Approximate 2026 geometry — Tier A/B compactness (Archived)

Archived (Superseded May 6, 2026). Prior to Elections Alberta's release of official 2026 shapefiles, the audit constructed a provisional three-tier geometry framework (Tier A/B/C) for compactness testing. All findings have been superseded by the canonical measurements reported in §5.4.9 using the official shapefiles. Technical methodology and version history at `analysis/methodology/commission_reference_shapes.md` and `archive/provisional_geometries/approximate_shape_analysis.md`.

Appendix F — Legal Interpretive Note

This audit does not offer a legal conclusion. It provides the evidentiary basis on which a legal challenge under *Saskatchewan Reference* [1991] 2 SCR 158's "effective representation" standard could be constructed. The question whether the minority proposal, or the advisory panel's map that the committee had to table by November 2, 2026, would satisfy the effective-representation requirement is for counsel and the courts to assess. The audit's core contribution is documenting :

1. The two commission proposals diverge systematically on five measurable dimensions.
2. The direction of divergence favours the governing party under the available vote inputs (one crosswalk probe excepted).
3. The process that set both proposals aside departs from comparator Canadian practice in specific ways.

These facts are reproducible from public data using checked-in code. They do not prove intent, and they do not by themselves establish a constitutional violation.

Admissibility and conduct posture

Admissibility of any expert evidence built on this audit's data is for counsel and a court to assess against the *R v Mohan* [1994] 2 SCR 9 / *White Burgess Langille Inman v Abbott and Haliburton Co.* [2015] 2 SCR 182 framework. The audit does not pre-adjudicate that question. The author's posture is the following:

- **The data and code are public and reproducible.** Except where noted (RT1, the §5.9.6 sub-claims, the submission archive), every number in this monograph is recoverable by an independent analyst running the publicly committed scripts against the publicly available Elections Alberta inputs. A skeptical analyst can assess methodological choices directly without depending on the author's interpretation.
- **The registration record is on OSF** (nine registrations: w2s8k, r3zm7, qsgy8, 6pt83, 9wp5y, yvc7g, s58a6, he53s, u47bq), with OSF's own timestamps; drand rounds only seeded the random number generators. §4.3.3 sets out which tests came before their results: the

commission-map results are exploratory. The tests for the November map were written down in June 2026, before that map existed, and amended on November 2–7, 2026 (Amendments 7–13, `findings/pre_registration_amendment_log.md`), after the committee tabled the panel's report. Amendments 7–10 were written before any of the panel's geometry was scored; Amendments 11–13 were written after results had been seen, and 12 and 13 each say "Not blind".

- **Conflict-of-interest disclosure is on file in the cover-page CoI block** and in `analysis/methodology/reference/conflict_of_interest.md`. The disclosure records the author's voting and donation history across parties, the author's election-day work as a contract election officer for Elections Alberta, the absence of any consulting relationship with the commission or any political party, and the self-funded nature of the research.
- **The author makes no representation regarding personal qualification as an expert witness.** If this audit's evidence becomes relevant to a constitutional proceeding, qualified counsel can engage independent experts in redistricting science, GIS, and electoral statistics to assess and present it.

Saskatchewan Reference framing. The "effective representation" standard established in *Reference re Provincial Electoral Boundaries (Saskatchewan)* [1991] 2 SCR 158 is permissive on deviation from population equality: McLachlin J (as she then was) wrote the guarantee of s. 3 is "the right to effective representation" (para. 26), with "relative parity of voting power" to be weighed against other factors, including "geography, community history, community interests and minority representation" (para. 33). Importantly, the Court provided no bright-line variance ceiling; instead, it requires a holistic assessment in which deviations are defensible *if justified by the specified non-quantitative factors.*

The standard has been applied in *Raîche v. Canada (Attorney General)*, 2004 FC 679, which examined the federal Electoral Boundaries Commission for New Brunswick's redrawing of Acadian boundaries. The Federal Court found **statutory** violations (ss. 15(1)(b) and 15(2) of the EBRA; Part VII of the Official Languages Act) and referred the boundaries back to the Commission. The Court did *not* find a Charter s.3 violation: applying the deference standard from *Reference re Prov. Electoral Boundaries (Sask.)*, [1991] 2 SCR 158 (the "*Carter*" standard, named for counsel Roger Carter QC — style of cause corrected 2026-06-12 per T1.7 R2 Ref #8; round-1 of the Raîche correction styled this as "*Carter v. Saskatchewan* [1991] 2 SCR 158," which is not the case's actual reporter caption), the boundary transfer survived the constitutional challenge. Earlier drafts of this report cited Raîche as a "s.3 strike-down" attributed to "Heneghan J." — both attributions were corrected 2026-06-12 per T1.7 Referee #8. Under the corrected Raîche reading: partisan asymmetry, standing alone, does not trigger either a Charter s.3 violation or an EBRA s.15(1)(b) statutory violation. Asymmetry becomes constitutionally or statutorily material only when paired with either (a) unjustified deviations from population parity unattributable to geography, community boundaries, or other statutory constraints, or (b) evidence permissible factors (geography, community of interest) have been distorted *in service of* partisan outcomes

rather than applied in service of the statute's non-partisan purposes. This is a *narrower* and more defensible doctrinal foundation than the prior framing claimed; it strengthens commission deference under *Carter* and places the analytical burden squarely on the audit's two-lane evidence rather than on the constitutional precedent.

Since *Canada (Minister of Citizenship and Immigration) v. Vavilov*, 2019 SCC 65, review of statutory interpretation is for reasonableness; *Dunsmuir v. New Brunswick*, 2008 SCC 9, had already collapsed the patently/manifestly-unreasonable distinction into a single reasonableness standard (wording corrected 2026-06-12 per T1.7 R2 Ref #12; earlier drafts here used the "manifest unreasonableness" vocabulary). Pal (2015) argues commission discretion is reviewable only at its outer margins. Commissioners operate within a broad "discretion space" including legitimate design preferences. The boundary between justified discretion and reviewable partiality turns on factual evidence about whether the stated non-partisan constraints genuinely drove the choices or were invoked post-hoc to rationalize a predetermined partisan outcome. The audit's findings — directional partisan asymmetry coupled with population-variance differences on the commission's 2024 tables (which almost disappear on the 2021 census, Appendix C), coupled with procedural departure from the pattern established by the majority under identical statutory constraints — are the kinds of evidence a court applying the effective-representation standard might weigh in assessing whether a commission's output exceeded justified margins of discretion. Whether the weighing produces a constitutional violation is for a court, not this audit, to determine.

Voter-impact translation of structural findings. The *Saskatchewan Reference* standard asks whether voters can exercise "effective representation," which requires districts enable rather than structurally impede the translation of votes into legislative representation. This paragraph translates the audit's structural findings into the specific voter-impact terms effective-representation analysis requires.

Population dispersion. The minority map's MAD of 4,707 persons (48% wider than the majority's 3,180) understates the individual voter effect. The minority's maximum positive deviation is +24.06%, corresponding to a district population of approximately 68,100 against the provincial mean of 54,929. A resident of the district commands 54,929 / 68,100 = 80.7% of the representative weight of a voter in a mean-population district — a dilution of roughly 19 percentage points. Three minority districts exceed +20% deviation (§5.1.1); none in the majority does. The majority's worst positive deviation is +14.28%, conferring 87.5% effective weight. Neither map breaches the ±25% statutory floor, and the *Saskatchewan Reference* standard explicitly permits deviation where justified by the enumerated factors. The question a court would weigh is whether the allocation of underweighted districts is spatially random (consistent with geographic necessity) or patterned (consistent with systematic placement). The audit's finding the minority's inflated districts concentrate in the Calgary Zone A geography (see below) is the evidence going to the patterning question.

Calgary zone asymmetry. Under the minority map, Zone A (NE / central Calgary — the NDP-competitive zone) averages 61,225 residents per district against Zone B (SW / S

Calgary) at 54,569 — a 12.2% intra-city gap. A resident of a Zone A district has 54,569 / 61,225 = 89.1% of the representative weight of a Zone B resident. Across 17 Zone A districts, this dilution structurally affects approximately 1,040,000 Calgary residents concentrated in the northeastern and central city. The majority produces no comparable patterned dilution (Zone A–Zone B gap 0.4%, or 205 persons). The minority gave a reason: it weighed electors as well as population in north-east Calgary (final report p. 310, "Electors as well as Population"). The commission majority rebutted that as "an extraneous consideration under the Act" (p. 63). Whether the reason justifies the variance is for a court. The gap is measured on the commission's 2024 tables; on the 2021 census the two maps' overall dispersion is almost level (Appendix C).

Airdrie community fragmentation. The minority map distributes the Airdrie region across four electoral districts (three by people). Airdrie (85,805 at the July 2024 municipal census per City of Airdrie 2024; 74,100 at the 2021 Census; 90,044 at the April 2025 municipal census — see §5.3.2 C1 footnote for full vintage reconciliation) is a single incorporated municipality with integrated planning jurisdiction, municipal services, and a distinct local economy. The minority's split leaves Airdrie one representative for whom it is the primary constituency (Airdrie-East) and sends about 45% of its residents to districts where Calgary residents outnumber them. The majority's 2-way split concentrates Airdrie's representation in two districts. Federally, Airdrie sits within one riding at a quota about twice the provincial one; that is context, not a benchmark (§5.9.3). Under *Saskatchewan Reference*, community of interest is a recognized justification for deviating from exact population parity; a configuration fragmenting a single community across four districts works against effective representation rather than in its service.

Conduct posture toward named-individual characterisations. This audit characterises the conduct of named public officials — Commission Chair Dallas K. Miller, Premier Danielle Smith, and the commissioners (Greg Clark, Susan Samson, John D. Evans KC and Dr. Julian Martin) — solely on the basis of those individuals' on-record statements in their public-official capacity, with each characterisation anchored to (a) a direct quotation of the public statement, (b) a primary-source citation, and (c) the audit's reasoning. Every characterisation appears alongside the underlying evidence so a reader can form an independent judgment. The audit does not investigate confidential deliberations, attribute motive without evidence, or characterise individuals in their private capacity. Whether any specific characterisation gives rise to a cause of action — under *Grant v. Torstar Corp.*, 2009 SCC 61, *WIC Radio Ltd. v. Simpson*, 2008 SCC 40, or otherwise — is for counsel and a court to assess on the actual record. The author does not pre-adjudicate that question and does not assert any defence in this monograph.

Appendix G — Mahalanobis D^2 Distribution: QQ-Diagnostic Against $\chi^2(4)$

The Channel 1 Mahalanobis p-value (8.80×10^{-7}) is computed as `scipy.stats.chi2.sf(D²,`

`df=4`), which assumes the ensemble's four-metric joint distribution is multivariate Gaussian, making D^2 approximately $\chi^2(4)$-distributed. One metric (seats@50/50) is discrete, so multivariate normality is approximate. This appendix documents a post-hoc empirical check of that approximation. The ensemble's plans have 87 districts and the scored maps 89, so the p-value is a cross-size comparison; a size-matched joint test is pending (§5.4.9).

Method. The same covariance matrix used by `joint_outlier_score_canonical.py` (sample mean, `np.cov(rowvar=False)`, `np.linalg.pinv`) was applied to all 1,010,000 canonical ensemble plans to compute a D^2 for each. A QQ-plot of the empirical D^2 quantile distribution against theoretical $\chi^2(4)$ quantiles is shown at `data/maps/mcmc/qqplot_mahalanobis_vs_chi2_4.svg` (generated by `analysis/scripts/mahalanobis_qqplot.py`). Quantiles were evaluated at 5,000 evenly spaced probability levels across [0.0001, 0.9999].

KS D-statistic. The Kolmogorov-Smirnov maximum CDF deviation between the empirical D^2 distribution and $\chi^2(4)$ is **D = 0.0076**. The KS p-value is not reported: with n = 1,010,000 observations it approaches zero for any trivial discrepancy regardless of practical fit quality, and the ensemble rows are not independent (n_eff ≈ 1,413 per the convergence diagnostics). A D below approximately 0.01–0.02 indicates a practically excellent fit; D = 0.0076 is comfortably within that range.

QQ-plot description. The bulk of the distribution — from $D^2 \approx 0$ through approximately the 99th percentile ($D^2 \approx 13.8$) — lies very close to the 45° reference line, indicating the $\chi^2(4)$ approximation is accurate throughout the mass of the distribution. At extreme percentiles the empirical tail is modestly heavier than $\chi^2(4)$ predicts: at the 99.0th percentile the empirical quantile is 13.76 against the theoretical 13.28; at the 99.9th it is 20.38 vs 18.47; at the 99.99th it is 24.83 vs 23.51. The departure is consistent with mild positive skew from the discrete seats@50/50 component.

Conservative or anti-conservative? A heavier empirical tail than $\chi^2(4)$ predicts means the empirical tail probability at any fixed D^2 threshold is larger than the parametric approximation returns. The parametric p-value therefore understates the true tail probability — an anti-conservative direction. The 4–10% above is a gap between quantiles; on the probability scale, where the p-value lives, the gap is larger. At the 2019 map's $D^2 = 13.16$, near $\chi^2(4)$'s 99th percentile, 1.22% of the 1,010,000 plans lie at or beyond it against the parametric 1.05% (§5.4.10; `findings/joint_empirical_bound_verification.json`). However, the minority map's observed $D^2 = 33.64$ (Mahalanobis distance 5.80) lies entirely outside the empirical envelope: the largest D^2 among all 1,010,000 canonical plans is 28.43. No plan in the ensemble approaches the minority observation. The empirical tail count at D^2_obs is zero (0 / 1,010,000). This does not contradict the parametric p: under $\chi^2(4)$, the expected number of ensemble plans at or beyond $D^2 = 33.64$ is $8.80 \times 10^{-7} \times 1{,}010{,}000 \approx 0.89$ plans, so observing zero is fully expected (Poisson $P(0 \mid 0.89) \approx 41\%$). Because the observation lies beyond the empirical range, no direct empirical p-value is estimable and the parametric approximation is the only available figure.

Practical conclusion. The $\chi^2(4)$ model provides an excellent fit through the broad body of the ensemble distribution (KS D = 0.0076, comfortably below the 0.01 threshold for an excellent fit; median 3.333 vs theoretical 3.357; the sample mean equals 4.000 by construction for D^2 and is not itself a fit diagnostic). Between the 99th and 99.99th percentiles the empirical quantiles sit roughly 4–10% above the theoretical ones; on the probability scale the departure is larger, so the true p-value in that region exceeds what the $\chi^2(4)$ formula returns by more than the quantile gap suggests. The minority map's $D^2 = 33.64$ lies beyond the empirical maximum of 28.43 across all 1,010,000 plans; the empirical tail count is 0. This is fully consistent with the parametric estimate: under $\chi^2(4)$, the expected number of ensemble plans at or beyond $D^2 = 33.64$ is $8.80 \times 10^{-7} \times 1{,}010{,}000 \approx 0.89$ plans, so observing zero is unsurprising (Poisson $P(0 \mid 0.89) \approx 41\%$). The anti-conservative tendency visible at the 99th–99.99th percentiles cannot be reliably extrapolated beyond the empirical maximum, so the quantitative effect on the headline p is unknown. The parametric assumption is defensible for this analysis: the departure in the observable tail is under 10% on the quantile scale and larger on the probability scale, the qualitative conclusion that the minority observation is extraordinarily rare under the neutral null is not sensitive to it, and the Hotelling T^2 n_eff-corrected p uses an F-distribution adjustment that does not rely on the large-sample $\chi^2(4)$ limit.

Draft. Falsifiability gates, robustness checks, and APSA citations documented throughout.

---

1. The minority map proposes a 4-way split of the City of Airdrie across Airdrie-East, Olds-Three Hills-Didsbury, Calgary-Airdrie, and Calgary-Foothills-Airdrie West; the majority proposes a 2-way split (Airdrie-East, Airdrie-West). (Corrected 2026-07-08: this footnote previously listed "Airdrie, Airdrie-Chestermere, Rocky Mountain House-Banff, Cochrane-Olds" and "Airdrie, Cochrane" — provisional-geometry-era district names. The corrected lists were recomputed by intersecting the Airdrie CSD boundary (`alberta_2021_csds.gpkg`) with the canonical shapefiles `ea_minority_2026_eds.gpkg` / `ea_majority_2026_eds.gpkg`, and match the Part III description in `reports/public/report_public.md`.) This structural divergence is documented and evaluated in §5.3.2 (packing/cracking-signature analysis) and §5.8.4 (community-of-interest splits). Federally (Representation Order 2023, quota about 115,000), Airdrie sits within one riding, Airdrie—Cochrane; at about half that quota it needs at least two provincial districts. This is context, not a benchmark (see §5.9.3). ↩
2. Both MADs are computed against the majority's mean (54,929) rather than each map's own mean (majority mean: 54,929; minority mean: 54,930). Using a common reference enables direct apples-to-apples comparison across maps. The 1-person difference is negligible: re-computing the minority MAD against its own mean of 54,930 produces 4,707 (unchanged at this precision level). ↩
3. **Canonical geometry recomputation, anchoring (2026-05-10) — full reconciliation note.** Pre-shapefile (DPG v0_10) result, computed April 2026: minority anchoring 14.5%, majority 71.0%, ratio 4.9× — reported during the audit as the structural lane's cleanest single

signal. Canonical recomputation (official Elections Alberta shapefiles, received 2026-05-06): minority 71.8%, majority 80.0%, 2019 baseline 75.1% — both 2026 maps close to the 2019 map; ratio 1.11×. The 4.9× gap is not a property of the official maps. **Mechanism of the DPG error**: `score_anchoring.py` measured the percentage of ED perimeter falling within 500 m of a Statistics Canada CSD edge (qsgy8 registered 50 m) on a per-segment basis during the DPG era; the ≥ 1 km run-length filter specified in the pre-registration landed on 2026-06-12, and `_measure_ring()` now applies it (see the §5.8.5 contiguity-filter disclosure); the canonical values above are filtered. The DPG pipeline preserved ED *area* to within ~0.0004% but did not constrain ED *boundaries* to lie on CSD polygon edges — the minority map's DPG approximation in particular was sourced from non-CSD reference geometry (road centrelines, census-tract proxies) and therefore failed the perimeter-alignment criterion even where the underlying area was correct. Area fidelity does not imply perimeter fidelity; this is a structural distinction in the DPG pipeline, not a hidden property of the minority map. The minority swung 14.5 → 71.8% (≈ 58 pp) while the majority swung 71.0 → 80.0% (≈ 9 pp) because the majority's DPG already had an official 2019 reference geometry available during construction, while the minority's was novel and had no reference shapefile to seed from. **Disposition in this audit.** The DPG-era anchoring finding (4.9× departure, cited in earlier drafts as the load-bearing structural signal) did not survive canonical recomputation and is not carried forward as a standalone result. The 4.9× figure did not stay in working drafts: it headlined the repository README at the April 27, 2026 release candidate, and the public OSF registration s58a6 (registered May 10, 2026, four days after the official shapefiles arrived) lists the anchoring channel as "4.9x below norm marginal finding; rigorous p-value pending" (registration text pinned by `responses_sha256` in `preregistration/osf_ledger.json`). The canonical recomputation superseded it. Where the DPG figures previously appeared in prose, the canonical values now appear instead. This footnote is the single preserved record of the DPG-era reading. The audit's structural case (§5.0.1, §6.2.2) now rests on the four geometry-independent dimensions: population dispersion (on the commission's 2024 tables, not on the 2021 census; Appendix C), Calgary zone asymmetry, Airdrie fragmentation, and chair-flagged spatial anomalies, plus the MCMC ensemble (Mahalanobis $p \approx 8.80 \times 10^{-7}$, a model estimate extrapolated past every sampled plan; the sample alone supports p below about 6.9×10^{-4}). For forward analysis and replication, readers should use the canonical geometry (official Elections Alberta shapefiles, SHA-256 verified via `analysis/utils/canonical_manifest.py`) as the authoritative substrate. Parallel canonical recompute deltas for partisan metrics are documented in `findings/post_audit_recompute_deltas.md`.
